REPORTS OF THE IMMIGRATION COMMISSION

CHANGES IN BODILY FORM
OF DESCENDANTS OF
IMMIGRANTS

(FINAL REPORT)

PRESENTED BY MR. DILLINGHAM

JUNE 8, 1911.—Ordered reprinted, with corrections
and illustrations

WASHINGTON
GOVERNMENT PRINTING OFFICE

1911

THE IMMIGRATION COMMISSION.

Senator WILLIAM P. DILLINGHAM,
Chairman.
Senator HENRY CABOT LODGE.
Senator ASBURY C. LATIMER.^a
Senator ANSELM J. MCLAURIN.^b
Senator LE ROY PERCY.^c

Representative BENJAMIN F. HOWELL.
Representative WILLIAM S. BENNET.
Representative JOHN L. BURNETT.
Mr. CHARLES P. NEILL.
Mr. JEREMIAH W. JENKS.
Mr. WILLIAM R. WHEELER.

Secretaries:

MORTON E. CRANE. W. W. HUSBAND.
C. S. ATKINSON.

Chief Statistician:

FRED C. CROXTON.

Extract from act of Congress of February 20, 1907, creating and defining the duties of the Immigration Commission.

That a commission is hereby created, consisting of three Senators, to be appointed by the President of the Senate, and three Members of the House of Representatives, to be appointed by the Speaker of the House of Representatives, and three persons to be appointed by the President of the United States. Said commission shall make full inquiry, examination, and investigation, by subcommittee or otherwise, into the subject of immigration. For the purpose of said inquiry, examination, and investigation said commission is authorized to send for persons and papers, make all necessary travel, either in the United States or any foreign country, and, through the chairman of the commission, or any member thereof, to administer oaths and to examine witnesses and papers respecting all matters pertaining to the subject, and to employ necessary clerical and other assistance. Said commission shall report to Congress the conclusions reached by it, and make such recommendations as in its judgment may seem proper. Such sums of money as may be necessary for the said inquiry, examination, and investigation are hereby appropriated and authorized to be paid out of the "immigrant fund" on the certificate of the chairman of said commission, including all expenses of the commissioners, and a reasonable compensation, to be fixed by the President of the United States, for those members of the commission who are not Members of Congress; * * *

^a Died February 20, 1908.

^b Appointed to succeed Mr. Latimer, February 25, 1908. Died December 22, 1909.

^c Appointed to succeed Mr. McLaurin, March 16, 1910.

LIST OF REPORTS OF THE IMMIGRATION COMMISSION.

- Volumes 1 and 2. Abstracts of Reports of the Immigration Commission, with Conclusions and Recommendations and Views of the Minority. (These volumes include the Commission's complete reports on the following subjects: Immigration Conditions in Hawaii; Immigration and Insanity; Immigrants in Charity Hospitals; Alien Seamen and Stowaways; Contract Labor and Induced and Assisted Immigration; The Greek Padrone System in the United States; Peonage.) (S. Doc. No. 747, 61st Cong., 3d sess.)
- Volume 3. Statistical Review of Immigration, 1819-1910—Distribution of Immigrants, 1850-1900. (S. Doc. No. 756, 61st Cong., 3d sess.)
- Volume 4. Emigration Conditions in Europe. (S. Doc. No. 748, 61st Cong., 3d sess.)
- Volume 5. Dictionary of Races or Peoples. (S. Doc. No. 662, 61st Cong., 3d sess.)
- Volumes 6 and 7. Immigrants in Industries: Pt. 1, Bituminous Coal Mining. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volumes 8 and 9. Immigrants in Industries: Pt. 2, Iron and Steel Manufacturing. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volume 10. Immigrants in Industries: Pt. 3, Cotton Goods Manufacturing in the North Atlantic States—Pt. 4, Woolen and Worsted Goods Manufacturing. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volume 11. Immigrants in Industries: Pt. 5, Silk Goods Manufacturing and Dyeing—Pt. 6, Clothing Manufacturing—Pt. 7, Collar, Cuff, and Shirt Manufacturing. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volume 12. Immigrants in Industries: Pt. 8, Leather Manufacturing—Pt. 9, Boot and Shoe Manufacturing—Pt. 10, Glove Manufacturing. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volume 13. Immigrants in Industries: Pt. 11, Slaughtering and Meat Packing. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volume 14. Immigrants in Industries: Pt. 12, Glass Manufacturing—Pt. 13, Agricultural Implement and Vehicle Manufacturing. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volume 15. Immigrants in Industries: Pt. 14, Cigar and Tobacco Manufacturing—Pt. 15, Furniture Manufacturing—Pt. 16, Sugar Refining. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volume 16. Immigrants in Industries: Pt. 17, Copper Mining and Smelting—Pt. 18, Iron Ore Mining—Pt. 19, Anthracite Coal Mining—Pt. 20, Oil Refining. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volume 17. Immigrants in Industries: Pt. 21, Diversified Industries, Vol. I. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volume 18. Immigrants in Industries: Pt. 21, Diversified Industries, Vol. II—Pt. 22, The Floating Immigrant Labor Supply. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volumes 19 and 20. Immigrants in Industries: Pt. 23, Summary Report on Immigrants in Manufacturing and Mining. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volumes 21 and 22. Immigrants in Industries: Pt. 24, Recent Immigrants in Agriculture. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volumes 23-25. Immigrants in Industries: Pt. 25, Japanese and Other Immigrant Races in the Pacific Coast and Rocky Mountain States. (S. Doc. No. 633, 61st Cong., 2d sess.)
- Volumes 26 and 27. Immigrants in Cities. (S. Doc. No. 338, 61st Cong., 2d sess.)
- Volume 28. Occupations of the First and Second Generations of Immigrants in the United States—Fecundity of Immigrant Women. (S. Doc. No. 282, 61st Cong., 2d sess.)
- Volumes 29-33. The Children of Immigrants in Schools. (S. Doc. No. 749, 61st Cong., 3d sess.)
- Volumes 34 and 35. Immigrants as Charity Seekers. (S. Doc. No. 665, 61st Cong., 3d sess.)
- Volume 36. Immigration and Crime. (S. Doc. No. 750, 61st Cong., 3d sess.)
- Volume 37. Steerage Conditions—Importation and Harboring of Women for Immoral Purposes—Immigrant Homes and Aid Societies—Immigrant Banks. (S. Doc. No. 753, 61st Cong., 3d sess.)
- Volume 38. Changes in Bodily Form of Descendants of Immigrants. (S. Doc. No. 208, 61st Cong., 2d sess.)
- Volume 39. Federal Immigration Legislation—Digest of Immigration Decisions—Steerage Legislation, 1819-1908—State Immigration and Alien Laws. (S. Doc. No. 758, 61st Cong., 3d sess.)
- Volume 40. The Immigration Situation in Other Countries: Canada—Australia—New Zealand—Argentina—Brazil. (S. Doc. No. 761, 61st Cong., 3d sess.)
- Volume 41. Statements and Recommendations Submitted by Societies and Organizations Interested in the Subject of Immigration. (S. Doc. No. 764, 61st Cong., 3d sess.)
- Volume 42. Index of Reports of the Immigration Commission. (S. Doc. No. 785, 61st Cong., 3d sess.)

LETTER OF TRANSMITTAL.

THE IMMIGRATION COMMISSION,
Washington, D. C., December 5, 1910.

To the Sixty-first Congress:

I have the honor to transmit herewith, on behalf of the Immigration Commission, a report entitled "Changes in bodily form of descendants of immigrants," which was prepared for the Commission by Franz Boas, professor of anthropology, Columbia University, New York. A partial report on this subject, by the same author, was transmitted to Congress December 16, 1909 (S. Doc. No. 208, 61st Cong., 2d sess.).

Respectfully,

WILLIAM P. DILLINGHAM,
Chairman.

CONTENTS.

	Page.
Introductory.....	1
CHAPTER I. General results of the investigation.....	5
Measurements of distinct types.....	9
Relations between time of immigration and change of type...	57
Rate of physiological development of foreign-born and Amer- ican-born.....	64
Probable causes of change in type.....	64
Problem of heredity.....	76
Phenomena of growth.....	78
Effect of size of family.....	79
II. Method of investigation.....	81
III. Color of hair.....	93
IV. Relations between bodily form and period of immigration.....	99
V. Investigations of the change of type, based on family observations.	117
VI. Growth.....	129
Physiological development.....	129
Growth of the head.....	137
VII. Heredity.....	153
VIII. Stature of children in families of different sizes.....	161
Appendix—Tabulations.....	167

LIST OF TABLES.

TABLE		Page.
1.	Cephalic index, or width of head expressed in per cent of length of head, of foreign-born and American-born Hebrews and Sicilians.	5
2.	Cephalic index of Hebrew and Sicilian boys: Foreign-born, those born in America within ten years after arrival of mother, and those born ten years or more after arrival of mother.	8
3a.	Measurements of foreign-born and American-born Bohemians.	10
3b.	Measurements of foreign-born and American-born Slovaks and Hungarians.	12
3c.	Measurements of foreign-born and American-born Poles.	14
3d.	Measurements of foreign-born and American-born Bohemians, Slovaks, Hungarians, and Poles, combined.	16
4.	Measurements of foreign-born and American-born Hebrews.	18
5.	Measurements of foreign-born and American-born Sicilians.	20
6.	Measurements of foreign-born and American-born Neapolitans.	22
7.	Measurements of American-born minus measurements of foreign-born: All types measured.	56
8.	Differences in head form of Hebrew males, between foreign-born, those born in America within ten years after arrival of mother, and those born ten years or more after arrival of mother.	58
9.	Cephalic index of foreign-born and American-born, arranged according to time elapsed between birth and immigration: Hebrews, Sicilians, and Neapolitans.	61
10.	Differences in stature and weight of Hebrew males, between foreign-born, those born in America within ten years after arrival of mother, and those born ten years or more after arrival of mother.	63
11.	Measurements of foreign-born Hebrews, men and women, according to year of immigration.	65
12.	Cephalic index of foreign-born and American-born for each year of immigration: Hebrews, Sicilians, and Neapolitans.	67
13.	Width of face of foreign-born and American-born adult Bohemians for each year of immigration.	69
14.	Excess of difference between parents and their American-born children over difference between parents and their foreign-born children: Bohemians, Hebrews, Sicilians, and Neapolitans.	70
15.	Width of face of foreign-born and American-born adult Bohemians arranged according to time elapsed between birth and immigration.	73
16.	Rate of growth of head.	78
17.	Stature of children of families of different sizes: Toronto, Ontario, and Oakland, Cal.	80
18.	Number of individuals measured.	84
19.	Test measurements of observers.	85
20.	Head measurements according to observers (adults).	87
21.	Differences between head measurements of single observers and general averages (adults).	91
21a.	Personal equations.	92
22.	Numerical values of hair colors of Hebrews.	94
23.	Numerical values of hair colors of Scotch.	95
24.	Numerical values of hair colors of Bohemians.	95
25.	Numerical values of hair colors of Sicilians.	96
26.	Comparison of numerical values of hair colors as obtained from different nationalities.	97
27.	Absolute numerical values of hair colors.	98

	Page.
TABLE 28. Average measurements of Hebrews born in various parts of eastern Europe.....	99
29. Years of arrival of foreign-born Hebrews.....	101
30. Years of arrival of mothers of American-born Hebrews.....	102
31. Comparison of foreign-born and American-born Hebrews born more or less than ten years after arrival of mother.....	104
32. Cephalic index of American-born Hebrew males (reduced to adults), according to time elapsed since immigration of mother.....	105
33. Cephalic index of foreign-born Hebrew males (reduced to adults), according to age at time of immigration.....	105
34. Number of years elapsed between immigration of mother and birth of American-born child (Hebrews).....	106
35. Cephalic index of Hebrews (reduced to adult males), according to year of immigration.....	108
36. Cephalic index of American-born Sicilians, males and females, (reduced to adult males).....	109
37. Cephalic index of foreign-born Sicilians (reduced to adult males).....	109
38. Correction for number of years elapsed between immigration of mother and birth of American-born child (Sicilians).....	110
39. Cephalic index of Sicilians (reduced to adult males), according to year of immigration.....	111
40. Cephalic index of American-born Neapolitans, males and females, (reduced to adult males).....	111
41. Cephalic index of foreign-born Neapolitans (reduced to adult males), according to age at time of immigration.....	112
42. Cephalic index of Neapolitans (reduced to adult males), according to year of immigration.....	113
43. Width of face of adult Bohemians arranged according to number of years between immigration and birth.....	114
44. Width of face of adult Bohemians (reduced to males), according to year of immigration.....	115
45. Summary of differences between parents and their own foreign-born children and parents and their own American-born children: 1, Bohemians; 2, Hebrews; 3, Sicilians; 4, Neapolitans.....	123
46. Differences in cephalic index between American-born Hebrew children (born ten years and more after arrival of mother) and their own parents.....	126
47. Excess of difference in cephalic index between American-born Hebrew children and parents over that between foreign-born Hebrew children and parents.....	127
48. Frequency of stages of pubescence of Hebrew boys.....	129
49. Measurements of Hebrew boys according to pubescence.....	130
50. Cephalic index according to age.....	138
51. Formulas showing decrease of cephalic index of foreign-born with increasing age.....	139
52. Formulas showing decrease of cephalic index with increasing age..	139
53. Length of head of adult males, Dresden I, calculated from measurements of children.....	140
54. Increments of length of head of males (from all available material).....	141
55. Increments of length of head of males in different European groups.....	142
56. Increments of length of head of females (from all available material).....	143
57. Increments of width of head (from all available material).....	144
58. Rate of decrease of cephalic index of males (from all available material).....	144
59. Length of head of males.....	145
60. Length of head of females.....	146
61. Width of head of males.....	147
62. Width of head of females.....	149
63. Cephalic index of males.....	150
64. Cephalic index of females.....	151
65. Variability of cephalic index of children, arranged according to differences in cephalic index between parents.....	154
66. Summary of correlations between parents and children.....	156
67. Correlation for length of head between parents and children (Hebrews).....	157

	Page.
TABLE 68. Correlation for width of head between parents and children (Hebrews).....	158
69. Summary of correlations between parents and children (Hebrews).....	159
70. Differences between statures of Toronto children of families of different sizes and the average stature of children for each age.....	161
71. Differences between statures of Oakland, Cal., children of families of different sizes and the average stature of children for each age.....	163
72. Average difference between statures of children of families of different sizes and average statures.....	165
73. Stature of Toronto boys, arranged according to number of deceased children per family.....	166

APPENDIX—TABULATIONS.

CHANGES IN BODILY FORM OF DESCENDANTS OF IMMIGRANTS.

By FRANZ BOAS.

INTRODUCTORY.

In March, 1908, I was intrusted by the United States Immigration Commission with an investigation of the physical characteristics of immigrants.

It seemed that the principal data to be collected in an investigation of this kind must relate to the differences in composition of the immigrants that arrive in this country at different periods, and to the changes that may take place among their descendants born in this country.

This problem is an exceedingly complicated one, on account of the great differences in type of the people that have immigrated into the United States from different parts of Europe, on account of the changes of social conditions under which these people lived at home and here, and on account of the extended intermixture of descendants of various nationalities that is taking place in the United States.

The investigations that have been carried on in Europe during the last fifty years have shown clearly that the types inhabiting various parts of Europe show fundamental differences, and that these differences are distributed, on the whole, more according to geographical localities than to nationalities. Thus the people of the Alps, no matter what language they may speak, show considerable similarities in type. On account of these local differences it seemed necessary to classify the immigrants according to their descent and country of origin; and in the initial stages of our inquiry we confined ourselves to a study of the east European Hebrew. When the essential points to be investigated became clearer by the results of this inquiry, the investigation was extended over Italians of that part of Italy south of Rome, Bohemians, and Hungarians, and, to a more limited extent, over immigrants of Scotch descent.

Since American environment differs very much in large cities, in small towns, and in the country, and again in different parts of the country, it seemed necessary to select a uniform American environment. Since, from a practical point of view, a knowledge of the influence of the life in congested parts of our cities seemed to be most important, this particular problem was selected for investigation.

According to our knowledge of anthropological conditions in the whole world, the form of the body seems to be the most stable characteristic of any given race of type. Indications have been found,

however, showing that under more favorable environment the physical development of a race may improve. This was shown by Gould and Baxter in their investigations of the physical characteristics of the soldiers enlisting during the War of the Rebellion, by H. P. Bowditch in his investigations of the development of Boston school children, and by similar investigations carried on at later times in various cities in America as well as abroad. No evidence, however, has been collected which would show an actual change in type due to the influence of environment. Where changes of this kind seem to occur—as, for instance, in a comparison of the types of city population and country population in Southern Germany and in Italy—the inclination of observers has been rather to attribute the difference either to the elective elimination of the weaker type or to the immigration of different types.

From a practical point of view it seemed all-important to know whether American environment had a favorable or unfavorable effect upon the descendants of immigrants.

The investigation has shown much more than was anticipated. There are not only decided changes in the rate of development of immigrants, but there is also a far-reaching change in the type—a change which can not be ascribed to selection or mixture, but which can only be explained as due directly to the influence of environment. This conclusion has been tested in many different ways, and seems to be amply proved. It has been stated before that, according to all our experiences, the bodily traits which have been observed to undergo a change under American environment belong to those characteristics of the human body which are considered the most stable. We are therefore compelled to draw the conclusion that if these traits change under the influence of environment, presumably none of the characteristics of the human types that come to America remain stable. The adaptability of the immigrant seems to be very much greater than we had a right to suppose before our investigations were instituted.

It is true that the investigation has been so fragmentary that only a very small part of the problem has been touched upon. It is only one kind of environment that has been investigated. Only a few of the European types have been tested, and none in numbers large enough to allow an inquiry into all the important details of our problem. The investigation has largely been confined to a study of the male sex, and the descendants of intermarriages among members of the same nationality only have been considered. By far the greater part of the work, therefore, remains to be done.

In carrying on this work I have been ably assisted by Dr. C. Ward Crampton, who organized the work in the New York schools. In the initial stages of the work I also greatly profited by conferences with Dr. Maurice Fishberg, whose investigations among the New York Jews indicated the practicability of the present investigation.

In planning the investigation it seemed desirable to select such measurements as would be most characteristic in defining the stage of development and the characteristic racial types of each group. The former question is most readily investigated by a study of the stature, weight, and general physiological development of the individual; the second, by a record of the length and width of the head,

width of the face measured between the zygomatic arches, and by color of hair, eyes, and skin. Accordingly these items were selected for our inquiry. At the same time it seemed necessary to obtain with the greatest possible accuracy the descent of the individual measured, and the record of his immigration. In the beginning we were planning to conduct our investigation largely in schools and colleges. For reasons which will presently be explained this plan had to be modified, but the blank for measurements as originally adopted contained the information regarding the school and grade in which the measurements were taken.

Considerable difficulty was encountered in the determination of the physiological development of the individual. According to my original plan, the condition of the teeth was to be observed, in order to determine the time of eruption of the permanent teeth as an indication of general physiological development. It seemed, however, impossible to carry through this investigation successfully, on account of the difficulty of finding a sufficient number of adequately trained observers. The inherent difficulties of observing the teeth are very considerable, and require a large amount of experience. The funds at our disposal not being sufficient to permit the engagement of experienced dentists, this part of the investigation was dropped.

In those New York schools in which bathrooms are established it was possible to obtain the weight of the children without clothing, and at the same time observations were made on pubescence as a means of determining the approximate physiological development. The method of these observations has been developed by Dr. C. Ward Crampton, but it is available only for the short period of adolescence.

The attempt was also made to collect material from American families settled in this country for several generations and living under more favorable conditions. I am indebted for the opportunity to collect material of this kind to the courtesy of Dr. Wilson Farrand, principal of the Newark Academy, who gave us permission to copy the full records which have been kept in his school for many years.

Much to my regret I have not been able to read proof of all the tables of the Appendix from the original tabulations. I have read the proofs of all the tables in the Report itself, and since I have found only 5 misprints I believe the figures in the Appendix may be considered as reasonably correct.

The first of these is the fact that the majority of the cases of this disease are reported from the United States and Europe. It is interesting to note that the disease is not reported from any of the tropical or subtropical regions of the world. This fact suggests that the disease is not a true tropical disease, but rather a disease of temperate climates.

The second of these is the fact that the disease is not reported from any of the large cities of the United States. This fact suggests that the disease is not a true urban disease, but rather a disease of rural areas. This is in contrast to many other diseases which are reported from large cities.

The third of these is the fact that the disease is not reported from any of the large cities of the United States. This fact suggests that the disease is not a true urban disease, but rather a disease of rural areas. This is in contrast to many other diseases which are reported from large cities.

The fourth of these is the fact that the disease is not reported from any of the large cities of the United States. This fact suggests that the disease is not a true urban disease, but rather a disease of rural areas. This is in contrast to many other diseases which are reported from large cities.

The fifth of these is the fact that the disease is not reported from any of the large cities of the United States. This fact suggests that the disease is not a true urban disease, but rather a disease of rural areas. This is in contrast to many other diseases which are reported from large cities.

The sixth of these is the fact that the disease is not reported from any of the large cities of the United States. This fact suggests that the disease is not a true urban disease, but rather a disease of rural areas. This is in contrast to many other diseases which are reported from large cities.

CHAPTER I.

GENERAL RESULTS OF THE INVESTIGATION.

In most of the European types that have been investigated the head form, which has always been considered one of the most stable and permanent characteristics of human races, undergoes far-reaching changes coincident with the transfer of the people from European to American soil. For instance, the east European Hebrew, who has a very round head, becomes more long-headed; the south Italian, who in Italy has an exceedingly long head, becomes more short-headed; so that in this country both approach a uniform type, as far as the roundness of the head is concerned.

The head form may conveniently be expressed by a number indicating the transversal diameter (or width of the head) in per cents of the diameter measured from forehead to the back of the head (or the length of the head). When the head is elongated (that is, narrow when seen from the front, and long when seen in profile), this number will be low; when it is rounded (that is, wide when seen from the front, and short when seen in profile), this number will be high. The width of the head expressed in per cents of the length of the head is about 78 per cent among Sicilians born in Sicily and about 83 per cent among Hebrews born in eastern Europe. Among Sicilians born in America this number rises to more than 80 per cent, while among east European Hebrews born in America it sinks to 81 per cent.

This fact is one of the most suggestive discovered in the investigation, because it shows that not even those characteristics of a race which have proved to be most permanent in their old home remain the same under the new surroundings; and we are compelled to conclude that when these features of the body change, the whole bodily and mental make-up of the immigrants may change.

These results are so definite that, while heretofore we had the right to assume that human types are stable, all the evidence is now in favor of a great plasticity of human types, and permanence of types in new surroundings appears rather as the exception than as the rule.

The disagreement of the changes in distinct types may be illustrated by Table 1 and figure 1 following, which show the head form of Sicilians and east European Hebrews of American birth in comparison with that of Sicilians and east European Hebrews of European birth.

The diagram shows very clearly that the two types are quite distinct in Europe and that their descendants born in America differ from their parents in opposite directions.

FIG. 1.—Comparison of head form of American-born and foreign-born Hebrew and Sicilian males. Scale, 1 square=0.5 unit.

The measurements of males of 5 years of age and older are indicated in this diagram. The head form, expressed by the ratio between width and length of head, and its change with increasing age, is indicated by the four lines. The diagram shows that foreign-born Sicilian males have the lowest value for this ratio and the foreign-born Hebrews the highest, while the American-born Hebrews and the American-born Sicilians stand between these two extremes, and are more alike than foreign-born individuals of the same types.

○ In order to understand the causes which bring about these alterations of type, it is necessary to know how long a time must have elapsed since the immigration of the parents to bring about a noticeable change of type of the offspring. This investigation has been carried out mainly for the cephalic index, which during the period of growth of the individual undergoes only slight modifications. It appears in those cases that contain many individuals whose parents have been residents of America for a long time that the influence of American environment upon the descendants of immigrants increases with the time that the immigrants have lived in this country before the birth of their children.

I have proved this statement by comparing the features of individuals of a certain type born abroad, born in America within ten years after the arrival of the mother, and born ten years or more after the arrival of the mother. It appears that the longer the parents have been here, the greater is the divergence of the descendants from the European type. The development may be illustrated by a comparison of Hebrews and Sicilians. The approach of the Hebrew and Sicilian types becomes very clear when we divide the American-born descendants into those born less than ten years after the arrival of the mothers and those born ten years or more after the arrival of the mothers. Since adult American-born Italians are few in number, it seemed best to compare individuals of an average age of about 9 years. Table 2 and figure 2, next presented, show the results of this comparison.

TABLE 2.—Cephalic index of Hebrew and Sicilian boys; foreign-born, those born in America within 10 years after arrival of mother, and those born 10 years or more after arrival of mother.

Type and age.	Cephalic index.	Average age.	Cases.
SICILIAN.			
Foreign-born boys 5 to 12 years old.....	79.5	9.6	241
American-born boys 5 to 19 years old:			
Born less than ten years after arrival of mother.....	80.9	10.0	375
Born ten years and more after arrival of mother.....	81.8	9.5	127
HEBREW.			
American-born boys 7 to 10 years old:			
Born ten years and more after arrival of mother.....	82.3	9.2	290
Born less than ten years after arrival of mother.....	82.4	9.2	257
Foreign-born boys 7 to 10 years old.....	84.6	9.1	179

FIG. 2.—Comparison of head form of Hebrews and Sicilians, arranged according to time elapsed between birth and immigration.

At 1 is indicated the head form expressed by the ratio between width and length of head of foreign-born Hebrews and Sicilians; at 2, the same ratios for those born within ten years after the arrival of their mothers in the United States; at 3, the corresponding values for those born more than ten years after the arrival of their mothers in America. The diagram shows the very rapid approach of the two types among children born shortly after the arrival of their mothers in America, and the slower continuation of this approach among children born a long time after the arrival of their mothers in America.

In figure 3 the form of the head of Sicilians and Hebrews is shown as seen from above. In the upper row the more rounded form of the foreign-born Hebrew is placed side by side with the more elongated form of the Sicilian. Below these is shown the head form of the descendants of the Hebrews and Sicilians born more than ten years after the arrival of the mothers. This figure is intended only

to give an impression of the change in proportions. It does not represent the head forms in other directions in detail.

FIG. 3.—Sketches of head forms.

Showing (1) the average form of the head of the foreign-born Hebrew; (2) the average form of the head of the foreign-born Sicilian; (3) the average form of the head of the American-born Hebrew and Sicilian born more than ten years after the arrival of the mother in America. These sketches are intended only to give an impression of the change in proportions. They do not represent the head forms in detail.

MEASUREMENTS OF DISTINCT TYPES.

In the following pages a condensed tabulation and graphical representation of the measurements of various types are given. (Tables 3-6, figs. 4-33). In the figures, Bohemians, Hungarians, Slovaks, and Poles are combined into one group. The numerical values of the hair-colors will be found explained on p. 98. The full tabulations will be found in the Appendix, Tables I-XVI, pp. 169-369.

FIG. 4a.—Statures of Bohemian and Hebrew boys. Scale, 1 square=0.5 cm.

In the diagram the growth of Bohemian boys is shown on the left; that of Hebrew boys on the right. The ages of the Bohemians should be read according to the italic figures; the ages of the Hebrews according to the roman figures placed in parentheses. The diagram shows that American-born boys of both these groups are, on the whole, better developed than foreign-born boys.

FIG. 4b.—Statures of Sicilian and Neapolitan boys. Scale, 1 square=0.5 cm.

In the diagram the growth of Sicilian boys is shown on the left; that of Neapolitan boys on the right. The ages of the Sicilians should be read according to the italic figures; the ages of the Neapolitans according to the roman figures placed in parentheses. The diagram shows no striking differences between the two groups.

FIG. 5a.—Statures of Bohemian and Hebrew girls. Scale, 1 square=0.5 cm.

In the diagram the growth of Bohemian girls is shown on the left; that of Hebrew girls on the right. The ages of the Bohemians should be read according to the italic figures; the ages of the Hebrews according to the roman figures placed in parentheses. The diagram shows that American-born girls of both these groups are, on the whole, better developed than foreign-born girls.

FIG. 5b.—Statures of Sicilian and Neapolitan girls. Scale, 1 square=0.5 cm.

In the diagram the growth of Sicilian girls is shown on the left; that of Neapolitan girls on the right. The ages of the Sicilians should be read according to the italic figures; the ages of the Neapolitans according to the roman figures placed in parentheses. The diagram shows that foreign-born girls of both these groups are, on the whole, better developed than American-born girls.

FIG. 6.—Excess of stature of American-born over foreign-born. Scale, 1 square=0.5 cm. Heavy lines indicate males; light lines, females.

In this diagram is shown the difference obtained by subtracting the stature of foreign-born individuals from that of American-born individuals. The heavy base lines indicate the difference 0. The diagram shows that among the Bohemians and Hebrews the difference is almost throughout positive, showing that in both sexes the American-born is taller than the foreign-born. Among the Sicilians the difference is decidedly under the 0 line, showing that the American-born Sicilian is not so favorably developed as the foreign-born. Among the Neapolitans the differences are irregular and small. The curve suggests, however, that among the Italians the unfavorable conditions are more marked in the females than in the males.

FIG. 7.—Weights of boys. Scale, 1 square = 0.5 kgm.

In this diagram the increase in weight of boys of the different nationalities is shown. The weights for the Bohemians should be read from the base-line 30.0, near the top of the diagram; those for the Hebrews, from the base-line 30.0 below the Bohemians; the weights for the Sicilians should be read from the base-line 30.0, under the Hebrews; while those for the Neapolitans should be read from the base-line 30.0, at the lower end of the diagram. The differences in weight are not very striking, but the increase in weight among American-born Hebrews is quite marked.

FIG. 8.—Excess of weight of American-born boys over foreign-born boys. Scale, 1 square=0.5 kgm.

In this diagram is shown the difference obtained by subtracting the weight of foreign-born individuals from that of American-born individuals. The heavy base-lines indicate the difference, 0. Only among the Hebrews does there appear to be any marked difference in favor of the American-born. Among the Sicilians the difference is markedly in favor of the foreign-born.

FIG. 9.—Length of head of foreign-born and American-born Bohemians. Scale, 1 square=0.5 mm.

Foreign-born boys.
 American-born boys.
 Foreign-born girls.
 American-born girls.

The diagram shows the increasing length of head of children from 5 years up. The upper two lines indicate the growth in length of head of boys; the lower two, the growth in length of head of girls. The diagram shows that the heads of American-born children are slightly longer than the heads of foreign-born children of the same ages.

FIG. 10.—Length of head of foreign-born and American-born Hebrews. Scale, 1 square=0.5 mm.

The diagram shows the increasing length of head of children from 5 years up. The upper two lines indicate the growth in length of head of boys; the lower two, the growth in length of head of girls. The diagram shows that the heads of American-born children, both boys and girls, are considerably longer than the heads of foreign-born children of the same ages.

- Foreign-born boys.
- - - American-born boys.
- Foreign-born girls.
- · - · American-born girls.

FIG. 11.—Length of head of foreign-born and American-born Sicilians. Scale, 1 square = 0.5 mm.

The diagram shows the increasing length of head of children from 5 years up. The upper two lines indicate the growth in length of head of boys; the lower two, the growth in length of head of girls. Since the values of this measurement do not differ very much among males and females, the two sets of lines have been separated. The measurements of the males should be read from the lines marked with roman numbers; those of the females, from the lines marked with italic numbers. The diagram shows that the heads of foreign-born children, both boys and girls, are longer than the heads of American-born children.

- Foreign-born boys.
- - - American-born boys.
- Foreign-born girls.
- American-born girls.

Fig. 12.—Length of head of foreign-born and American-born Neapolitans. Scale, 1 square = 0.5 mm.

The diagram shows the increasing length of head of children from 5 years up. The upper two lines indicate the growth in length of head of boys; the lower two, the growth in length of head of girls. Since the values of this measurement do not differ very much among males and females, the two sets of lines have been separated. The measurements of the males should be read from the lines marked with roman numbers; those of the females from the lines marked with italic numbers. The diagram shows that the heads of foreign-born children, both boys and girls, are longer than the heads of American-born children.

FIG. 13.—Excess of length of head of American-born over foreign-born. Scale, 1 square = 0.5 mm. Heavy lines indicate males; light lines, females.

In this diagram is shown the difference obtained by subtracting the length of head of foreign-born individuals from that of American-born individuals. The heavy base-lines indicate the difference 0. The diagram shows that the difference in the length of head for the Bohemian group is very slight. For the Hebrew, the head of the foreign-born is throughout longer than that of the American-born. Among the Sicilians and Neapolitans the reverse is the case.

FIG. 14.—Width of head of foreign-born and American-born Bohemians. Scale, 1 square=0.5 mm.

The diagram shows the increasing width of head of children from 5 years up. The upper two lines indicate the growth in width of head of boys; the lower two, the growth in width of head of girls. Since the values of this measurement are nearly the same for males and females, the two sets of lines have been separated. The measurements of the males should be read from the lines marked with roman numbers; those of females, from the lines marked with italic numbers. The diagram shows that the width of the head of American-born children, both boys and girls, is slightly less than the width of foreign-born children of the same ages.

- Foreign-born boys.
- - - American-born boys.
- Foreign-born girls.
- . - . American-born girls.

FIG. 15.—Width of head of foreign-born and American-born Hebrews. Scale, 1 square=0.5 mm.

The diagram shows the increasing width of head of children from 5 years up. The upper two lines indicate the growth in width of head of boys; the lower two, the growth in width of head of girls. Since the values of this measurement are nearly the same for males and females, the two sets of lines have been separated. The measurements of the males should be read from the lines marked with roman numbers; those of females, from the lines marked with italic numbers. The diagram shows that the width of the head of American-born children, both boys and girls, is considerably less than the width of the head of foreign-born children of the same ages.

FIG. 16.—Width of head of foreign-born and American-born Sicilians. Scale, 1 square = 0.5 mm.

The diagram shows the increasing width of head of children from 5 years up. The upper two lines indicate the growth in width of head of boys; the lower two the growth in width of head of girls. Since the values of this measurement are nearly the same for males and females, the two sets of lines have been separated. The measurements of the males should be read from the lines marked with roman numbers; those of females, from the lines marked with italic numbers. The diagram shows that the width of the head of American-born children is slightly more than the width of the head of foreign-born children.

- · - Foreign-born girls.
- American-born girls.

FIG. 18.—Excess of width of head of American-born over foreign-born. Scale, 1 square=0.5 mm. Heavy lines indicate males; light lines, females.

In this diagram is shown the difference obtained by subtracting the width of head of foreign-born individuals from that of American-born individuals. The heavy base-lines indicate the difference 0. The diagram shows that for the Bohemians the width of head is slightly less among the American-born than among the foreign-born. Among the Hebrews the excess of the foreign-born over the American-born is very marked. Among the Sicilians and Neapolitans the difference is, on the whole, positive, indicating an increased width of head among the American-born.

FIG. 19.—Cephalic index of foreign-born and American-born Bohemians. Scale, 1 square, 0.5 unit.

The diagram shows the change in cephalic index of children from 5 years up. The upper two lines indicate the cephalic index of boys; the lower two, that of females. Since the values of this measurement are nearly the same for males and females, the two sets of lines have been separated. The measurements of males should be read from the lines marked with roman numbers; those of females from the lines marked with italic numbers. The diagram shows that foreign-born children, both boys and girls, are slightly more round-headed than American-born children.

- American-born girls.

FIG. 23.—Excess of cephalic index of American-born over foreign-born. Scale, 1 square=0.5 unit. Heavy lines indicate males; light lines, females.

In this diagram is shown the difference obtained by subtracting the cephalic index of foreign-born individuals from that of American-born individuals. The heavy base-lines indicate the difference 0. The diagram shows that among the Bohemians and Hebrews the cephalic index of the foreign-born is greater than that of the American-born, the lines in both cases being below the 0-line. Among the Sicilians and Neapolitans the reverse is the case. The cephalic index of the American-born is greater than that of the foreign-born, the line being almost throughout above the 0-line.

FIG. 24.—Width of face of foreign-born and American-born Bohemians. Scale, 1 square=0.5 mm.

The diagram shows the increasing width of face of children from 5 years up. The upper two lines indicate the growth in width of face of boys; the lower two, the growth in width of face of girls. Since the values of this measurement are nearly the same for males and females, the two sets of lines have been separated. The measurements of the males should be read from the lines marked with roman numbers; those of females, from the lines marked with italic numbers. The diagram shows that the faces of foreign-born children, both boys and girls, are much wider than those of American-born children.

 American-born boys.
 Foreign-born girls.
 American-born girls.

FIG. 33.—Excess of pigmentation of American-born over foreign-born. Scale, 1 square = 0.5 unit. Heavy lines indicate males; light lines, females.

In this diagram is shown the difference obtained by subtracting the pigmentation of foreign-born individuals from that of American-born individuals. The heavy base-lines indicate the difference 0. The diagram shows that there are no material differences in the amount of pigmentation of the hair of foreign-born and American-born.

The features that have been studied are stature, weight, length of head, width of head, width of face, and color of hair. While it seems doubtful that changes in pigmentation occur, all the other features show notable differences. These are not in the same direction in all cases. Stature, weight, length of head, and width of head show increases in some cases, decreases in others; the width of the face decreases among all the types that have been studied, except the Scotch.

The types that have been subjected to examination are the Bohemians, Slovaks and Hungarians, Poles, Hebrews, Sicilians, Neapolitans, and Scotch. These have been selected because they represent a number of the most distinct European types, and because they constitute a large percentage of our immigrants. The changes that have been observed may be summarized as follows:

The Bohemians, Slovaks and Hungarians, and Poles, representing the type of central Europe, exhibit uniform changes. Among the American-born descendants of these types the stature increases and both length and width of head decrease, the latter a little more markedly than the former, so that there is also a decrease of the cephalic index. The width of the face decreases very materially.

The Hebrews show changes peculiar to themselves. Stature and weight increase; the length of the head shows a marked increase, and the width of the head decreases, so that the cephalic index decreases materially; the width of the face also decreases.

Sicilians and Neapolitans, representing the Mediterranean type of Europe, form another group which shows distinctive changes. These are less pronounced among the Neapolitans than among the Sicilians, who are also purer representatives of the Mediterranean type, notwithstanding the many mixtures of peoples that have occurred in Sicily and the adjoining parts of Italy. The stature of the Sicilians born in America is less than that of the foreign-born. This loss is not so marked among the Neapolitans. In both groups the length of the head decreases, the width of the head increases, and the width of the face decreases.

In Tables 3-6 (pp. 10-23), are given summaries of the measurements of immigrants and of their American-born descendants of various European types. In a number of figures the differences between American-born and foreign-born are represented, the heavy line in each diagram representing the difference 0, the points above this line positive differences, those below the line negative differences (see fig. 6, p. 28; fig. 8, p. 30; fig. 13, p. 35; fig. 18, p. 40; fig. 23, p. 45; fig. 28, p. 50; fig. 33, p. 55).

The summaries here presented are in part based on very limited material, and for this reason the differences between foreign-born and American-born do not appear as regular as they would presumably appear if a larger number of cases were available. Nevertheless the tables, as well as their graphic representation, show that there is a regular tendency towards the occurrence of the same kind of differences between foreign-born and American-born.

In order to obtain a better expression for the quantitative difference between the two groups, I have assumed that the difference between foreign-born and American-born is the same for all ages—an assumption which may serve well enough for a first approximation. The differences thus obtained for each year and sex have been weighted according to the number of cases, and in this way the following characteristic differences among the various groups have been obtained:

TABLE 7.—*Measurements of American-born minus measurements of foreign-born, weighted according to number of cases: All types measured.*

Race and sex.	Length of head.	Width of head.	Cephalic index.	Width of face.	Stature.	Weight.

Scotch:						
Males.....	+1.4	-0.5	-0.8	-1.5	+1.8	39
Females.....	-0.3	+0.3	+0.2	+1.9	+3.9	53

The table shows in the case of every type except the Scotch certain decided differences between the measurements of individuals born in America and the measurements of those born abroad. There appear to be three distinct groups. The central European type, represented in our series by the Bohemians, Hungarians, Slovaks, and Poles, shows a decrease of the cephalic index for those born in America, which is due to a decrease of both length of head and width of head. The width of face shows a considerable decrease, while the stature increases. The Hebrews differ in their behavior from the preceding group in showing a much larger decrease in cephalic index, which is due to the fact that the length of the head increases, while the width of the head decreases. The decrease in width of face is also considerable, and the stature shows a marked increase. The third group is formed by the two south Italian divisions—the Neapolitans and Sicilians. In both of these cases we find an increase of the cephalic index, which is more marked among the long-headed Sicilians than among the more round-headed Neapolitans. This increase is due to a widening of the head, combined with a loss in length. The face of both groups also loses in width. The stature of the American-born is less than the stature of the foreign-born. These data show that the changes in the dimensions of the head do not depend by any means upon the absolute or relative measurements which are found among the foreign-born, but that heads which are nearly of the same length, like those of the Bohemians and of the Hebrews, behave quite differently in this country, the length of the one increasing, while the length of the other decreases.

It seems best to defer the discussion of the significance of these remarkable phenomena until the characteristics of the change in type have been brought out from different points of view.

RELATIONS BETWEEN TIME OF IMMIGRATION AND CHANGE OF TYPE.

The differences in type between the American-born descendant of the immigrant and the European-born immigrant develop in early childhood and persist throughout life. This is indicated by the general occurrence of the typical differences in the measurements of children of all ages. (See Tables 3-6.) The influence of American environment makes itself felt with increasing intensity, according to the time elapsed between the arrival of the mother and the birth of the child. In Table 8 and figure 34 I have compared the measurements of the foreign-born child, of the child born within ten years after the arrival of the mother, and of the child born ten years or more after the arrival of the mother, with the general average of children of that particular race. The table shows clearly the strong and increasing effect of American environment.

FIG. 34.—Comparison of head measurements of foreign-born and American-born Hebrew children.

In this diagram the measurements of the total series of Hebrew children, born both abroad and in America, have been considered as the norm, which is indicated by the zero line in each diagram. The differences between this norm and the measurements of foreign-born children, of children born in America less than ten years after their mother's arrival, and of those born in America ten or more years after their mother's arrival are shown. The diagram indicates that for the length of head, foreign-born children remain throughout below the norm; that children born soon after their mother's arrival in America exceed the norm; and that children born a long time after their mother's arrival are still more in excess of the norm. For the width of the head, width of the face, and cephalic index these conditions are reversed. These measurements of the foreign-born child are above the norm, while those of the American-born child are below the norm, the more so the longer the mother has been in America before the birth of the child. In all four diagrams the difference between the foreign-born and those born in America less than ten years after the mother's arrival is greater than the corresponding difference between the two groups of American-born.

A more detailed study of these phenomena illustrates still more clearly the increased modification of the descendants of immigrants born a long time after the arrival of their parents in America. Among the Hebrews the cephalic index of the foreign-born is practically the same, no matter how old the individual at the time of immigration. This might be expected when the immigrants are adult or nearly mature; but it is of interest to note that even children who come here one year or a few years old develop the cephalic index characteristic of the foreign-born. This index ranges around 83. When we compare the value of this index with that of the index of the American-born, according to the time elapsed since their immigra-

tion, we find a sudden change. The value drops to about 82 for those born immediately after the immigration of their parents, and drops to 79 in the second generation, i. e., among the children of American-born children of immigrants. In other words, the effect of American environment makes itself felt immediately, and increases slowly with the increase of the time elapsed between the immigration of the parents and the birth of the child.

The conditions among the Sicilians and Neapolitans are quite similar to those observed among the Hebrews. The cephalic index of the foreign-born remains throughout on almost the same level. Those born in America immediately after the arrival of their parents show an increase of the cephalic index. In this case the transition, although rapid, is not quite so sudden as among the Hebrews, probably because among the Italians born within a year before or soon after immigration, there is some doubt as to the place of birth. These uncertainties are due to the habit of the Italians to migrate back and forth between Italy and America before finally settling here, and to the indefiniteness of their answers in regard to the place of birth of the child, which sometimes had to be inferred from the age of the child and the year of immigration of the mother. As long as this uncertainty exists, which is hardly present at all in the data relating to the Hebrews, it does not seem necessary to assume any other cause for the more gradual change of the cephalic index about the time of immigration.

The Italian immigration is so recent that individuals who have been born many years after the arrival of their parents in America are very few in number, and no individuals of the second generation have been observed. For this reason it is hardly possible to decide whether the increase of the cephalic index continues with the length of time elapsed between the immigration of the parents and the birth of the child. These conditions appear clearly in Table 9 and figure 35.^a

^b Foreign-born.

^c American-born.

a, Hebrews; b, Sicilians; c, Neapolitans.

FIG. 35.—Cephalic index of foreign-born and American-born (reduced to adult males), arranged according to time elapsed between birth and immigration. Scale, 1 square=0.5 unit.

These diagrams show that the cephalic index of the foreign-born Hebrews (to the left of the 0-point) ranges about the value 82.6. For those born at the time of immigration of their parents there is a sudden drop, which continues to the right of the 0-point until gradually a value a little below 80 is reached. The corresponding curve giving the values for the Sicilians shows lower values until the time of immigration, and a sudden rise after immigration. Similar conditions prevail among the Neapolitans, but the difference between the foreign-born and American-born is not so marked.

Among the east European Hebrews the American environment, even in the congested parts of the city, has brought about a general more favorable development of the body, which is expressed in the increased height of body (stature) and weight of the children. The Italian children, on the other hand, show no such favorable influence of American environment, but rather a small loss in vigor as compared to the average condition of the immigrant children. It therefore appears that the south Italian race suffers under the influence of American city life, while the east European Hebrew develops under these conditions better than he does in his native country. It seems that the change in stature and weight increases with the time elapsed between the arrival of the mother and the birth of the child. This is indicated by the increased differences between children born more than ten years after the arrival of the mother, as compared to those born less than ten years after the arrival of the mother (Table 10, fig. 36).

FIG. 36.—Comparison of stature and weight of foreign-born and American-born Hebrew children.

In this diagram the stature and weight of the total series of Hebrew children, born both abroad and in America, have been considered as the norm, which is indicated by the zero line in each diagram. The difference between this norm and the stature and weight of foreign-born children, of children born in America less than ten years after their mother's arrival, and of those born in America ten or more years after their mother's arrival are plotted. The diagram shows that both stature and weight of foreign-born children are under the norm; that those of children born less than ten years after their mother's arrival are near the norm, while those of children born more than ten years after their mother's arrival are above the norm. In this case the difference between children born less than ten years and those born more than ten years after the arrival of their mother is greater than the difference between foreign-born children and those born within ten years after their mother's arrival.

RATE OF PHYSIOLOGICAL DEVELOPMENT OF FOREIGN-BORN AND AMERICAN-BORN.

The data collected show apparently that American-born boys reach maturity slightly earlier than foreign-born boys, while the period of childhood is exactly the same among the foreign-born and American-born children. This method was first applied by Dr. C. Ward Crampton. (See p. 129 et seq.)

PROBABLE CAUSES OF CHANGE IN TYPE.

The explanation of these remarkable phenomena is not easy. Whatever their causes may be, the change in form can not be doubted. It might, however, be claimed that the causes are no deep, physiological changes, but due to the changes of certain external factors. It is obvious that a change in the composition of the immigrants of a certain region that have arrived in America at different times might bring it about that the people who came here at different periods had distinct physical characteristics, and that those are now reflected in the descendants of the older generations when compared with those of the more recent immigrants.

I have carried through an investigation of the absolute measurements of the Hebrews. Although the results are not quite convincing, it would seem that after the panic of 1893 a decrease in the general development of the immigrant appeared, which continued for several years. These observations are contained in Table 11 and figure 37, in which for each period the difference between the measurement for all the immigrants and for those arriving during each period are given.

TABLE 11.—*Measurements of foreign-born Hebrews, men and women, according to year of immigration.*

Period of arrival.	Stature.	Length of head.	Width of head.	Cephalic index.	Width of face.
	<i>Cm.</i>	<i>Mm.</i>	<i>Mm.</i>		<i>Mm.</i>
1880.....	-0.5	+1.7	+1.5	+0.1	+3.5
1880-1884.....	-0.8	+0.2	+0.7	+0.0	+1.6
1885-1889.....	+0.5	+1.2	+0.3	-0.4	+0.4
1890-1894.....	+0.1	+1.6	+0.4	-0.5	+0.2
1895-1899.....	-0.9	-1.2	-0.3	+0.3	-0.4
1900-1904.....	+0.7	-0.9	-0.4	+0.2	-0.7
1905-1909.....	±0.0	-0.3	+0.1	+0.1	-1.2

A further investigation of the cephalic index has shown that this measurement as observed among Bohemians, Hebrews, Sicilians, and Neapolitans, immigrating at different periods between 1860 and 1909, is almost constant, so that the annual differences can not account for the change of type of the descendants of immigrants. This result has been obtained, first, by a direct comparison of types immigrating at different periods. Furthermore, I have compared the cephalic index of all immigrants of a certain year and that of their descendants. I have tabulated in the same manner the width of face of Bohemians. It appears from these tabulations, Tables 12 and 13, figures 38 and 39, that the differences which are exhibited by the whole series exist also between the immigrants who arrived here in a certain year and their descendants.^a The purely statistical explanation of the phenomenon may therefore be dismissed.

It may be remarked here that the stature of Sicilians and Neapolitans is considerably more than those recorded by Livi for enlisted soldiers. According to Livi^b these values range for the districts in question from 1626 to 1635 mm. Here it must be remembered that all individuals under 154 cm. are excluded from the army, and that in all the lower values a considerable elimination occurs which will depress the average stature by fully 0.5 cm. The difference between the American and European value is, therefore, about 2.5-3 cm., which seems more than can be allowed for the shoes, the American measurement being taken with shoes. It would require a further study to determine whether any selection of taller individuals has taken place.

^a See pp. 108, 111, 113.

^b *Autropometria Militare*, p. 267.

FIG. 37.—Comparison of measurements of immigrants arriving in America at different periods.

In this diagram the average measurements of all adult immigrants, males and females, have been taken as a norm, and the differences between immigrants arriving at different periods and the general norm have been plotted. On the whole, the diagram does not show any striking changes in type, although the change in the width of face requires explanation. The most striking feature of the diagram is the general decrease in all measurements in the period following the year 1894, which indicates that the arrivals during the period following the panic of 1893 were underdeveloped in every direction. The increase in the cephalic index during the same period does not contradict the data contained in the other curves, because the index is not an absolute measurement, but the ratio between length of head and width of head. A preliminary tabulation of the measurements after 1907 shows a similar decrease to the one noted here. This decrease is perhaps due to the panic of 1907.

FIG. 39.—Width of face of foreign-born and American-born adult Bohemians for each year of immigration. Scale, 1 square=0.5 mm.

The diagram shows that the width of face of the American-born is much less than that of the foreign-born.

In order to overcome all possible objections based on the assumption of a different composition of the immigrant series and of the American-born series, I have also compared the measurements of parents and their own foreign-born and American-born children. The results of this tabulation are contained in Table 14. The figures contained in this table were obtained in the following manner: For each year the difference between father and his American-born son, father and his American-born daughter, mother and her American-born son, and mother and her American-born daughter, were determined; and these were compared with the series giving the same differences for the parents and their foreign-born children. After these differences had been obtained for each year and for the

four possible combinations of sexes, the difference obtained for parents and their American-born children was compared with the difference between parents and their foreign-born children, the latter being subtracted from the former. Since the parents of both groups, foreign-born and American-born, are of the same type, when the American-born child has a larger measurement than the foreign-born child the difference of the values compared will be negative, and when the measurement of the American-born is less than that of the foreign-born the difference will be positive. The values in Table 14 were obtained by averaging the results for all ages and for all combinations of sexes. It will be seen that the results of the observations agree with the results obtained by the generalized comparison of the foreign-born and American-born, as given in Table 7. Among the Bohemians, for instance, we find the stature increased, all the other measurements decreased; among the Sicilians we find stature, length of head, and width of face decreased, while width of head and cephalic index increase. This shows clearly that an actual difference between the two groups must have developed.

TABLE 14.—*Excess of difference between parents and their American-born children over difference between parents and their foreign-born children: Bohemians, Hebrews, Sicilians, and Neapolitans.*

Measurements.	Bohe- mians.	Hebrews.	Sicilians.	Neapolitans.

Width of face (mm.).....	+1.04	+2.10	+1.33	+1.55

More difficult to investigate is the hypothesis that the mechanical treatment of infants may have a decided influence upon the form of the head, and that the changes in cradling and bedding which are made by immigrants almost immediately after their arrival in America account for the changes of head form. If this were true, the continued changes among the Hebrews might indicate merely that the American method of cradling is used the more frequently the longer the family has resided in this country. A number of investigators have claimed that the position of the child on the back tends to produce short-headedness, and that the position on the side tends to produce long-headedness.^a There is good evidence that a flattening of the occiput occurs when a very hard pillow is used and the child lies permanently on its back. This is the case, for instance, among many Indian tribes; and similar results might obtain if a swathed child were to lie permanently on its back. The prevalence of rachitis in New York would favor distortion due to pressure. While I can not disprove the existence of such influences, I think weighty considerations are against their acceptance. If we assume that among the Hebrews the children born abroad have a lesser length of head than those born here, because they are swathed and lie more permanently on their backs than the American-born children who can move about freely,

^aG. Walcher, Ueber die Entstehung von Brachy- und Dolichocephalie (Zentralblatt für Gynäkologie, 1904, XXIX, No. 7).

we must conclude that there is a certain compensatory decrease in the other diameters of the head of the American-born. Since this compensation is distributed in all directions, its amount in any one direction will be very small.^a The decrease in the width of head that has been observed is so large that it can not be considered simply as an effect of compensation; but we have to make the additional hypothesis that the American-born children lie so much on their sides that a narrowing of the head is brought about by mechanical pressure. The same considerations hold good in all the other types. If, therefore, in one case the greater freedom of position of the child increases the length of its head, it is difficult to see why, among the Bohemians, the same causes should decrease both horizontal diameters of the head, and why, among the Sicilians, the length should decrease and the width increase.

Dr. S. Breitenfeld, who is familiar with the treatment of infants both in Bohemia and in New York City, informs me that in Bohemia new-born children are swaddled from the shoulders down. During the first four or six weeks of life the arms are also tied to the body. The Bohemian claims that the swathing serves to keep the limbs straight. The head is covered with a cap made, among the well-to-do, of lace, and among the poor, of muslin or other material. The object of the cap is said to be to keep the ears close to the head, but the pressure exerted by the cap is very slight only. The head rests on a soft pillow made of feathers or down. The child is carried about on a cushion (*Steckkissen*). The swaddling is continued for five or six months. The Bohemians, on coming to America, do not give up the custom of swaddling right away, but it is gradually discontinued. Children are carried for baptism almost always in swaddling clothes. The cushions used by the Bohemians in America are, on the whole, harder than those used by Bohemians abroad. On the whole it seems probable that Bohemian children born abroad lie more regularly on their backs on soft cushions than do American-born children, who move more freely but lie on harder cushions. The Bohemian Hebrews give up the custom of swathing their children much more rapidly than the Bohemians.

Doctor Breitenfeld also believes that rachitis is much more common among Bohemian children living abroad than among Bohemian children living in New York, and that in Bohemia itself rachitis is more common in the country than in the cities.

Dr. Maurice Fishberg had the kindness to give me the following information:

In eastern Europe the Slavs, as well as the Jews, swathe their new-born infants with roller bandages from the shoulders down to the ankles. The infant is usually kept flat on its back on a soft pillow. This swathing is continued for at least three months, often as long as six, and even longer when the infant is of poor vitality. I do not believe that the horizontal position in which these infants are kept has any influence on the shape of their heads. The fact that the pillows on which they are kept are quite soft, made as they invariably are of feathers or even down, precludes any effective pressure on the occiput. Indeed, there is hardly any difference in the pressure on the occiput between swathed and other children. They are often turned on their sides. In New York City the immigrants discard swathing completely. Among thousands of infants seen by me in my practice I never saw one swathed.

^a See F. Boas, *The Cephalic Index* (American Anthropologist, N. S., vol. I [1899], p. 448 et seq.).

Rickets, atrophy, malnutrition, scrofula, etc., are quite common among the Jews in eastern Europe. The fact that they are town dwellers almost exclusively and have an appalling proportion of poor and destitute, coupled with a high fecundity, explains it. In Wilna, Dr. S. Kowarsky (*Wratchebnaia Gazeta*, No. 20, 1908) shows that Jewish infants are more often rickety than the Christians in that city. The same is true of other cities in Russia, Poland, and Roumania. In New York City the reverse is true. The proportion of Jewish infants with rickets is much less than among non-Jewish infants of the same social and economic status. The reasons are the improvement in their economic conditions, as compared with eastern Europe, as well as the fact that comparatively few mothers go out to work after marriage, rarity of artificial feeding, etc. It appears to me that the Italian children in New York City very often suffer from rickets, probably more often than in southern Italy.

Dr. Antonio Stella has had the kindness to give me the following information in regard to the treatment of Italian children:

Neapolitan and Sicilian children are swathed, the bandages extending from the shoulders down. For several months the arms are tied to the body, while later the bandaging continues from the chest downward. The swaddling is generally continued until the children are weaned. The mattress of the child is made of wool, and the pillow is either made of wool or of feathers. It would seem that, according to description, the pillow is harder than that used by the Hebrews and Bohemians. During the hot season the children are left freer than in winter. They are not carried about on cushions, but in the arms of the mothers. After immigration the Italians do not give up the custom of swaddling children, but continue for years the same habits to which they are accustomed in Europe.

The question whether the heads of children of immigrants are more plastic than those of the foreign-born children, owing to greater frequency of rachitis, can not easily be answered. Doctor Breitenfeld believes that rachitis is much more common among European Bohemians than among Bohemians in New York City, while Doctor Stella asserts that the reverse is true among the Italians; but, even allowing for the greater plasticity, the treatment of the infant would not explain in a simple manner the changes that have been observed.

The development of the width of the face seems to my mind to show most clearly that it is not the mechanical treatment of the infant that brings about the changes in question. The cephalic index suffers a very slight decrease from the fourth year to adult life. It is therefore evident that children who arrive in America very young can not be much affected by American environment in regard to their cephalic index. On the other hand, if we consider a measurement that increases appreciably during the period of growth, we may expect that in children born abroad but removed to America when young, the total growth may be modified by American environment. The best material for this study is presented by the Bohemians, among whom there are relatively many full-grown American-born individuals. The width of face of Bohemians, when arranged according to their age at the time of immigration, shows that there is a loss among those who came here as young children—the greater the younger they were. Continuing this comparison with the American-born, born one, two, etc., years after the arrival of their mothers, the width of face is seen to decrease still further. It appears therefore that the American environment causes a retardation of the growth of the width of face at a period when mechanical influences are no longer possible. This is shown by Table 15 and figure 40.

^a Foreign-born.

^b American-born.

FIG. 40.—Width of face of foreign-born and American-born adult Bohemians arranged according to time elapsed between birth and immigration. Scale, 1 square=0.5 mm.

The diagram shows that the width of face of individuals who were born more than ten years before their arrival here ranges about 142.5 mm. From here on a gradual decrease in the width of face sets in, which continues among those born in America.

I have not carried through the analogous investigation for stature, because in this case the increase might simply be ascribed to the better nutrition of most of the north and central European immigrants after their immigration into this country.

There is another hypothesis which might account for the observed changes of type. If it were assumed that among the descendants of

immigrants born in America there are an appreciable number who are in reality children of American fathers, not of their reputed fathers, a general assimilation with the American type would occur. Socially this condition is not at all plausible, but on account of the importance of the phenomenon that we are discussing it should be considered. I do not think that any of the observations that have been made are in favor of this theory. The changes that occur in the Bohemians who arrive here as young children, the different directions of the changes in distinct types, particularly the shortening of the head of the Bohemians and of Italians, do not favor the assumption. Furthermore, if the modification were due to race mixture the similarity between fathers and American-born children should be less than the similarity between fathers and foreign-born children. There is no indication that this is the case, for the index of correlation which expresses the degree of similarity is about the same in either group, 0.37 between fathers and foreign-born children, 0.39 between fathers and American-born children. (See p. 154 et seq.)

That the index of correlation is a sensitive index of similarity and, we may say, of purity of sexual relations, is shown by the correlation for color of hair between Hebrew mothers and daughters, which is exceptionally low (0.13 for 616 cases), because many mothers wear wigs, and perhaps some daughters dye their hair.

This hypothesis is also shown to be untenable by the comparisons of fathers and mothers with their own foreign-born and American-born children. These comparisons show that the differences are the same in the case of fathers and children and of mothers and children, so that obviously the same conditions must control the relations between fathers and their children and mothers and their children. In other words, the fathers must be considered as the true fathers of their children.

It seems to my mind that the changes that have been observed in the transition of Europeans to the environment of New York must be considered as analogous to those that the European rural population undergoes when it moves from the country to the city. Ammon,^a who was the first to observe these changes in Baden, ascribes them to the effects of natural selection, which weeds out among the south Germans that move to the city the more short-headed type, while the long-headed type survives. Livi,^b who made similar observations in Italy, believed that the changes are simply due to the wider range of territory from which urban populations are drawn. The more varied descent, from which the urban population is derived, brings it about that in a region inhabited by short-headed people the urban population will be more long-headed, while in a region inhabited by long-headed people it will be more short-headed, than the rural population.

I believe that this factor is of considerable importance in the development of differences between urban and rural population; but our American observations show that there is also a direct influence at work. Ammon's observations are in accord with those on our American city-born central Europeans; Livi's, with those on our American

^aNatürliche Auslese beim Menschen, 1893. Zur Anthropologie der Badener, 1899, pp. 431 et seq. and 615 et seq.

^bAntropometria Militare, 1896.

city-born Sicilians and Neapolitans. Parallel observations made in rural districts and in various climates in America, and others made in Europe, may solve the problem whether the changes that we have observed here are only those due to the change from rural life to urban life. From this point of view the slight changes among the Scotch are also most easily intelligible, because among them there is no marked transition from one mode of life to another, most of those measured having been city dwellers and skilled tradesmen in Scotland, and continuing the same life and occupation here.

On the whole, it seems more likely that the phenomena observed in the cities of Europe and among the descendants of immigrants in America are analogous, but not the same; that both are expressions of the general plasticity of human types when living under different conditions. The variability of the Hebrew type in different parts of Europe, which has been so clearly demonstrated by Maurice Fishberg,^a is also in favor of this theory. Doctor Fishberg has shown that the Hebrew type in various parts of eastern Europe varies somewhat, and generally in accordance with the type of the surrounding population. He was inclined to interpret this phenomenon as due to intermixture, but it may well be an expression of the effect of environment upon the same type.

It may be possible that the wider range of intermarriages which occur in America may have an effect upon human types. The actual intermarriages in small villages in Europe are preponderantly of such character that the same strain will persist for a long period with very slight disturbance by intermixture from outside, the majority of intermarriages in small communities being generally in that community. When immigrants leave their home and settle in large cities this permanence of strain is entirely broken; and it seems at least possible that the changes which have been noticed in urban types, both in Europe and in America, may in part be due to this cause. Our present views of heredity would make it plausible that a disturbance of the established type would occur in such a case, even if the two intermarrying types are not markedly distinct. It has not been possible up to this time to investigate the material thoroughly from this point of view; but I believe the theory deserves to be followed up. Modifications in the distribution of sexes have been observed in an analogous case in the Argentine Republic, where it has been shown that in intermarriages between Spaniards and Italians the proportion of the sexes changes materially. The information contained in our material will permit us to investigate the question here suggested.

Earnest advocates of the theory of selection might claim that all these changes are due to the effects of changes in death rate among foreign-born and American-born; that either abroad or here individuals of certain types are more liable to die, and that thus these changes are gradually brought about. On the whole, it seems to my mind, the burden of proof would lie entirely on those who claim such a correlation between head index, width of face, etc., and death rate—a correlation which I think is highly improbable, and which could be proposed only to sustain the theory of selection, not on account of

^aMaterials for the Physical Anthropology of the Eastern European Jews (Mem. Am. Anthr. Ass., Vol. I., 1905, p. 1 et seq.).

any available facts. I grant the desirability of settling the question by actual observations, but until these are available we may point out that the very suddenness of the changes after immigration, and the absence of changes due to selection by mortality among the adult foreign-born, would require such a complicated adjustment of cause and effect in regard to the correlation of mortality and bodily form that the theory would become improbable on account of its complexity.

It would be saying too much to claim that all the distinct European types become the same in America, without mixture, solely by the action of the new environment. First of all, we have investigated only the effect of one environment, and we have every reason to believe that a number of distinct types are developing in America. But we will set aside this point and discuss only our New York observations. Although the long-headed Sicilian becomes more round-headed in New York and the round-headed Bohemian and Hebrew more long-headed, the approach to a uniform general type can not be established, because we do not know yet how long the changes continue and whether they would all lead to the same result. I confess I do not consider such a result as likely, because the proof of the plasticity of types does not imply that the plasticity is unlimited. The history of the British types in America, of the Dutch in the East Indies, and of the Spaniards in South America favors the assumption of a strictly limited plasticity. Certainly our discussion should be based on this more conservative basis until an unexpectedly wide range of variability of types can be proved. It is one of the most important problems that arise out of our investigation to determine how far the instability or plasticity of types may extend.

Whatever the extent of these bodily changes may be, if we grant the correctness of our inferences in regard to the plasticity of human types, we are necessarily led to grant also a great plasticity of the mental make-up of human types. We have observed that features of the body which have almost obtained their final form at the time of birth show modifications of great importance in our new surroundings. We have seen that others which increase during the whole period of growth, and are therefore subject to the continued effect of the new environment, are modified even among individuals who arrive here during their childhood. From these facts we must conclude that the fundamental traits of the mind, which are closely correlated with the physical condition of the body and whose development continues over many years after physical growth has ceased, are the more subject to far-reaching changes. It is true that this is a conclusion by inference; but if we have succeeded in proving changes in the form of the body, the burden of proof will rest on those who, notwithstanding those changes, continue to claim the absolute permanence of other forms and functions of the body.

PROBLEM OF HEREDITY.

In the course of our investigation it has been necessary to inquire into certain problems which have no immediate connection with the change of type of the descendants of immigrants, but which are of great importance for our knowledge of the amalgamation of different types in America. The most important of these is the problem of heredity.

Two theories of heredity are being held. In accordance with one, the children show a tendency to revert to a type intermediate between the types of the two parents—a mid-parental type—or, in cases of changes of types, to another type dependent upon the mid-parental type. In other words, the characteristics of the parents are blended in the children. According to the other theory, the laws of heredity act rather in such a way that, in regard to certain traits, either the father's or the mother's type, or the type of a more remote ancestor, is reproduced, and that certain parental traits may be dominant over others. In a generalized way we may say that by dominance is meant the tendency of one particular trait—either the father's or the mother's—to appear with greater frequency in the children than the corresponding but different trait of the other parent. It does not necessarily follow that all the traits of the same type are dominant, but dominant traits may be present in both parents, some in one, some in the other.

In a mixed population, like that of America, in which the frequencies of mixtures increase with the increasing social amalgamation of the descendants of immigrants, these questions are of prime importance, and it seemed desirable to obtain as much information as possible on this point.

An inquiry into the values of the cephalic index has shown clearly that the type of heredity in intermarriages in the same race is that of alternating heredity. Children do not form a blend between their parents, but revert either to one type or to the other. The method by means of which this problem has been investigated is based on the consideration that in case children show a tendency to revert to a type intermediate between that of father and mother, the variability of all the children in each family must remain the same, no matter what the difference between father and mother may be. On the other hand, if there is a reversion to the parental types, we must expect that the variability of the children in each family will increase with the difference in type between the two parents. The actual calculation of these data requires a reduction of the results according to the number of children to each family. After this reduction was made and the cephalic index of the mother reduced to corresponding male values, it was found, that, when the difference between the parents was—

From 0-2.9 units, the variability of the children was. . \pm 6.8 units. . (1102 cases).

From 3-5.9 units, the variability of the children was. . \pm 6.7 units. . (736 cases).

From 6-8.9 units, the variability of the children was. . \pm 8.3 units. . (317 cases).

9 units and more, the variability of the children was. \pm 13.0 units. . (108 cases).

No evidence has been obtained showing that one type is dominant, but all show equal degrees of correlation between father and child and between mother and child and for various values of the cephalic index.

The exact character of the alternating inheritance can not be established from the data at our disposal. Although a large number of families have been investigated, they are all families consisting of father and mother belonging to the same type, and consequently cases of great differences between the parents are rare; and these are the ones which bring out the facts of alternating inheritance most clearly. It seems from the discussion of the available data

that in the type of heredity investigated—that is, of the cephalic index among members of the same type of man—the facts agree best with the theory which assumes the absence of dominant traits in the type, an equal frequency of reversion to the parental types, a lesser reversion to ancestral types, and the existence of a family type (genotype).

PHENOMENA OF GROWTH.

It has also been found necessary to investigate the phenomena of growth. The older investigations of Bowditch, Roberts, Peckham, Porter, and myself, not to mention many later ones, have shown that there is a period of marked acceleration of growth during the period of adolescence. Our inquiries have demonstrated that a similar period of acceleration occurs in the growth of the head, most markedly in the growth of the length of the head, and that the period is synchronous in both sexes with the rapid increase in the bulk of the body. The occurrence of this period of acceleration of growth during the period of adolescence is of interest because the periods of rapid growth of different parts of the body are not by any means the same throughout. (Table 16, figure 41.)

The material for this investigation was obtained from the tables published by Röse,^a Ranke,^b Boas,^c and by use of the tables of the Immigration Commission.

TABLE 16.—Rate of growth of head.

a, Length of head; b, width of head; c, cephalic index.

FIG. 41.—Rate of annual growth of length of head, width of head, and cephalic index. Scale, a, b, 1 square=0.5 mm.; c, 1 square=0.5 unit.

This diagram shows that both length of head and width of head have first a decreasing rate of growth, then a more rapid growth during adolescence, followed by a gradual decrease in rate of growth. The maximum rate at the period of adolescence seems to be, for girls, at about 12 years; for boys, between 15 and 16 years.

For the cephalic index the greatest rapidity of change in boys is also about 15 years.

The cephalic index develops in a peculiar way. It is about constant during the early years of life, but during the period of adolescence it shows a rapid decrease in both sexes. (See p. 137 et. seq.)

EFFECT OF SIZE OF FAMILY.

Among the influences upon the physical development of children that have been studied, the size of the family deserves especial mention on account of the tendency of American-born families to decrease in size. Children of small families in Toronto, Ontario, are taller than those of families of larger size. The same phenomenon exists in Oakland, Cal., where the average size of the family is much smaller than in Toronto. About the same proportions prevail among children of families of one, two, three and more children, as in Toronto.

The differences obtained from the measurements in both cities, weighted according to the number of cases, are given in the table and figure following:

TABLE 17.—*Stature of children of families of different sizes: Toronto, Ontario, and Oakland, California.*

	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.	11.	12.
Excess of stature over norm	+0.21	+0.10	+0.05	±0.00	-0.05	-0.06	-0.14	-0.11	-0.12	-0.23	-0.05	-0.29
Weight	1,057	2,189	3,006	3,119	2,626	2,001	1,253	865	475	307	136	54

FIG. 42.—Comparison of the statures of children in families of different sizes. Scale, 1 square=0.02σ

In this diagram the average stature of children in families of all sizes has been assumed as a normal. The number of children per family is indicated on the horizontal line; the excess or defect in stature by the distances between the broken line and the normal. It appears that children in families that have one child only have a considerable excess in stature; that the stature of children in families of from two to four sinks to the normal, while the stature of children in larger families is considerably below the normal. (The figures in Table 19 do not quite agree with those given on the diagram, on account of corrections made in the table after the diagram had been completed.)

The numerical values express the excess in stature in multiples of the standard variability. In order to reduce them to centimeters, each value ought to be multiplied by about 6. It appears from these data that the physical development of children, as measured by stature, is the better the smaller the family. It is generally assumed that the increase in stature among the groups that are better situated economically is due to better nutrition than is found among the poor. The general economic advance is also believed to account for the general increase in stature in Europe. I am inclined to lay much greater stress upon the decrease in the frequency of diseases of childhood, which have a retarding influence upon growth that can not be made up after the detrimental causes have been overcome, and it may well be that lesser frequency of diseases brings about the better development of children in small families, although the one-child families might be expected to form an exception from this point of view.

CHAPTER II.

METHOD OF INVESTIGATION.

The following blank was used for recording the measurements:^a

Date of Observation.....	Observer.....
Place of Observation.....	School.....
Name.....	Grade or class.....
Date of Birth: Day..... Month.....	Year.....

In order to insure greater uniformity, three observers were sent to each school in which measurements were taken, and in these schools a considerable number of control measurements were made in order to test the uniformity of the observers. On the whole, the results of these tests were perfectly satisfactory. Where any doubt arose, which was the case particularly in some measurements of the width of face, these measurements were eliminated.

The investigation of the material obtained in the schools showed remarkable differences in type among the children, according to the period elapsed between the arrival of their parents in this country and their own birth. These differences were so peculiar and unexpected that it seemed indispensable to control the results by direct comparisons between the children and their own parents. For this reason the school measurements were supplemented by extended series of measurements of whole families, the observers making a house-to-house canvass, measuring families of immigrants, with their consent. Naturally, a considerable amount of opposition was offered to observers from time to time, and I wish to acknowledge here with thanks the assistance of the Italian, Jewish, and Bohemian newspapers in urging the members of these various nationalities to submit to being measured. In schools statures were measured without shoes. In family measurements it was unfortunately impossible to have the shoes removed.

The instruments used for our measurements were a wooden height-measure consisting of three pieces, with a movable cross-arm divided into centimeters; a pair of steel calipers, similar in type to Broca's head-calipers, with dulled point; a standard of hair-colors made by Messrs. B. Dickson & Co., of New York. The attempt to utilize Martin's eye-colors was not as successful as might have been desired. No samples of eye-colors were used in the extended investigation on account of the great expense involved in the purchase of a sufficient number of sets. No standards were used for the determination of the skin-color, and for this reason skin-color and eye-color have not given results of great value.

It was my plan to select only a few of the most distinct European types for our investigation, and to observe these as nearly as possible in the same type of environment, namely, in the congested districts of New York City. Owing to the localization of various nationalities and the general scattering of the north Europeans, the social environment in New York under which the various types have been collected is not quite the same. The Hebrew material was almost entirely collected on the lower east side of New York City. Only a small part was obtained from the neighborhood of Fifth avenue in Harlem. The Italian material was collected in large part in the neighborhood of Chatham Square, but a considerable portion was obtained on the upper east side of New York City, and a small portion in Yonkers.

The Bohemian material was collected on the east side, between Third and First avenues between Seventieth and Eighty-fourth streets. The Hungarian, Polish, and Slovak material was largely obtained in Brooklyn.

The way in which the people live together, and the failure of some of the observers to understand clearly the orders given for their work, have brought it about that there is a considerable amount of scattering material. I desired, for instance, to confine the Italian investigation to Sicilians and people from the extreme southern end of the Italian

peninsula; but the way in which Neapolitans and Sicilians live together would have caused such difficulties and delays in collecting data, that it seemed best to collect both groups at the same time, and to discriminate later. In the case of the Bohemians it was my desire to confine the investigation as strictly as possible to that nationality, because the identification of the descent of Slovaks, Hungarians, Poles, and Ruthenians entails considerable difficulties, the disentanglement of which requires considerable time. Unfortunately the district visited by one of the observers was to a very great extent Hungarian and Slovak rather than Bohemian, and before a change could be made a large body of Hungarian data had been collected. Most of the Slovak and Hungarian material was obtained from the families from northwestern Hungary, and for this reason a distinction between the two nationalities was entirely out of the question, the information given not being sufficiently distinct to show whether the people were of Slovak or of Hungarian descent.

The Polish material which was obtained is very much mixed. The large body is from Galicia, Prussian Poland, and the southwestern part of Russian Poland, but mixed in appear a considerable number of Lithuanians and of white Russians.

In a preliminary investigation I have compared the types of these three groups (Bohemian, Hungarian and Slovak, and Poles), which, on the whole, appear to be so uniform that they might well be classed together; but since the differences between foreign-born and American-born, which are the essential object of our inquiry, are rather small, it seemed best to select material as homogeneous as possible, and for this reason the Bohemians, Slovaks and Hungarians, and Poles have each been treated as one single group.

The last two series are rather few in number, but the results obtained are quite in accord with those obtained for the Bohemians.

Unfortunately the collection of Scotch data proved to be very laborious and slow, on account of the scattering of members of this nationality all over the city. For this reason the series is very short, and the results obtained from their discussion require further corroborative evidence.

The statistical information obtained is as accurate as may be expected under the circumstances. While, on the whole, the place of birth of the parents of the individuals measured could be determined with a fair degree of accuracy, the place of birth of the grandparents was very difficult to ascertain, particularly in the case of school children. The year of immigration was generally given by the individuals questioned as a certain number of years ago, and while fairly accurate, can not be taken as absolutely certain. A particular difficulty was caused in the case of the Italians by the fact that both parents, but mostly the father, came to America a number of times, and that the informant sometimes gave the year of his first arrival here as the year of immigration; sometimes that of his arrival here for permanent residence. This has also led to a certain amount of uncertainty in regard to the place of birth of children who were born very near the time of immigration of their parents. In some cases this information, as explicitly given, is contradicted by the statement in regard to the year of arrival of the parents, which may be a year or so different from the one obtained from the statement regarding the place of birth of the children. The ages, par-

ticularly those of women, are also not absolutely certain; but since the adults over 26 years of age have not been classified, these errors have no effect upon our results. While the sociological data can not be assumed as absolutely correct, their discussion shows clearly that on the average they may be taken as representing the true conditions.

Judging from the care that has been taken in obtaining statistical information and from the character of the observers, I believe that the errors in regard to time of immigration, place of birth, and descent contained in our blanks are no greater than those obtained by the enumerators of the census. I do not hesitate to express this opinion, on account of the expressions of opinion of some careful census enumerators who had also worked for the anthropometrical division of the United States Immigration Commission. The total number of cases observed for each nationality, sex, and age is as follows:

Owing to the necessity of collecting material in time for the present report, the work had to be pushed with considerable energy, and it was necessary to train observers for taking these measurements. In all, thirteen observers were engaged in this work, and particular

pains were taken to make their measurements comparable. The measurers were required to measure one another from time to time. In Table 19, I give the results of these measurements, taken on the first and fourth Saturdays in May, 1909. The vertical columns of the table indicate the measurements of the same observer; the horizontal lines, the measurements taken by each observer on the others. It will be seen from this table that all the deviations are small, and that the material may be considered as quite accurate. The names of the observers are indicated by their initials.

It seems desirable to control the measurements also by the results obtained by different observers on individuals of the same groups.

The determination of the personal equation may be made by comparing the average obtained by each observer with the true value of the whole series. It may be assumed that the personal equations (ϵ) of the observers are distributed according to the laws of chance. The differences between the averages of each observer (a) and the total average (A) consist of the accidental error x and the personal equation ϵ .

$$A - a = x + \epsilon.$$

If we indicate averages by brackets, the mean square value

$$\begin{aligned} [(A - a)^2] &= [(x + \epsilon)^2] \\ &= [x^2] + [\epsilon^2]. \end{aligned}$$

Since $[x^2] = \frac{\sigma^2}{n}$, where σ is the standard deviation of the measurement in question, and n the number of observations, we find

$$[(A - a)^2] = \frac{\sigma^2}{n} + [\epsilon^2].$$

The general average may therefore be found by giving the average obtained by each observer the weight

$$w = \frac{1}{\frac{\sigma^2}{n} + [\epsilon^2]}.$$

Table 20 (pp. 87-90) gives the results of all observations obtained by various observers on adults of various human types and the number of cases on which these averages are based.

Approximate values of A have been calculated by utilizing those series in which the number of observations made by each observer were fairly large. In this way the following values for $[\varepsilon^2]$ were obtained:

	Male.	Female.	Total.
Length of head mm. ²	0.8	0.2	0.5
Width of head.....	.3	.4	.4
Width of face.....	.4	.7	.5

Based on these, the weighted averages A for each nationality represented in our series have been calculated, and are given in the last line in Table 20 (pp. 87-90). Table 21 (pp. 91, 92) contains the differences between head measurements of single observers and the general weighted averages.

From these the personal equations given in Table 21a (p. 92) have been calculated.

I mention again that statures were taken in schools in stocking-feet; in families, with shoes.

CHAPTER III.

COLOR OF HAIR.

The color of hair was determined by comparing the hair over the forehead with locks of hair of different colors, extending from black to flaxen. The samples were 17 in number. Besides these, there were 8 different shades of reddish hair, beginning with a very light color and extending to a very dark-reddish hue. These were marked with the numbers from 18-25. Unfortunately I was later on unable to match in additional samples the color 12, so that the sample is missing in the observations made on Bohemians, Slovaks, Poles, and Hungarians.

There were so few individuals with hair of a red color that the subdivision of the reds has not been utilized in our tabulations.

The different samples of black, brown, and blond represent essentially one kind of pigment, which is present in different intensities. If, therefore, the whole series from black to flaxen can be divided into equal intervals, it will be possible to determine numerically the color of the hair.

My attempts to find samples of hair which gave the impression of equal color contrasts, beginning with the darkest and extending up to the lightest, were unsuccessful, because the different colors of hair could not be found either in the New York market or in the European market. For this reason I was compelled to utilize a series of colors which had arbitrary distances, and which were numbered from 1 to 17.

It seems possible, however, to ascribe to these colors numerical values.

Our whole experience justifies the assumption that the distribution of different degrees of pigmentation follows in general the law of probabilities—the exponential law. If this is true, it is always possible to determine with accuracy at what distance from the average value of the whole series a certain point is situated, provided we know the frequencies with which the event in question occurs below and above the selected point. For instance, if all colors darker than 4 were found to occur with a frequency of 16 per cent, we know from the tables giving the values of frequencies conforming to the probability curve that the color 4 will represent the value of the average minus the mean square variability. I have determined in this manner the numerical values for every sample of hair from the distribution of hair-colors among the Hebrews. The frequencies of the observations will be found in Table 22 (p. 94).

The values of the multiples of the mean square variation, which will be found in the fifth column of our table, were taken from Shepard's table of the integral of the probability function, published in the second volume of "Biometrika."

TABLE 22.—Numerical values of hair-colors of Hebrews.

17.....	3	0.0
18-25.....	92
Total.....	4,305

The result here obtained means that the point up to which hair-colors are classed as belonging to No. 1 will be 2.58 σ removed from the average color. It is obvious that values obtained in this tabulation are the more inaccurate the farther they are removed from the average, because in these cases a slight difference in the relative frequency of a certain color brings about very large differences in the multiple of σ to which they belong.

The average numerical value of the color belonging to any one of the numbers may now be determined by calculating the average value of the intervals corresponding to the color-numbers. This average equals—

$$\frac{\int_{x_1}^{x_2} \frac{x}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} dx}{\int_{x_1}^{x_2} \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} dx} = \frac{\frac{1}{\sqrt{2\pi}} (e^{-x_1^2} - e^{-x_2^2})}{\int_{x_1}^{x_2} \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} dx}$$

and these values can easily be calculated from the table above referred to, which contains both the ordinates and the integrals of the probability curve. In this manner the averages contained in the last column of Table 22 have been calculated.

In order to show that the numerical values thus obtained are applicable, we have to make an analogous tabulation from the hair-colors obtained among other people. The tabulation of the Scotch gives the following results:

TABLE 23.—Numerical values of hair-colors of Scotch.

Number of hair-color.	Cases.	Per cent.	Total percentage of all cases from 17 to—	Multiple of σ .	Average for each in multiple of σ .

Total.....	2,978				

In order to compare the results of these series, we have to designate each color as equal to the average of the particular series plus or minus certain multiples of σ ; and if we designate the average of the Hebrews as a_1 , that of the Scotch a_2 , those of the Bohemians and Sicilians as a_3 and a_4 , respectively, the standard variation of the Hebrews σ_1 , that of the Scotch σ_2 , of the Bohemians σ_3 , of the Sicilian σ_4 , we find from the preceding tables, for instance,

$$\text{For no. 2:} \quad a_1 + 1.88\sigma_1 = a_2 + 2.02\sigma_2 = a_3 + 2.15\sigma_3 = a_4 + 1.04\sigma_4$$

$$\text{For no. 3:} \quad a_1 + 1.15\sigma_1 = a_2 + 1.17\sigma_2 = a_3 + 1.59\sigma_3 = a_4 + 0.34\sigma_4$$

These values may be weighted according to the accuracy of the determination of each multiple of σ . While the probabilities from which σ is determined are the less accurate the nearer the probability is to 0.5, the accuracy of σ increases very much with the approach of the value of 0.5. Without attempting an entirely satisfactory weighting of the multiples of σ , an adequate method of weighting may be obtained by observing the amount of change in the value of σ which corresponds to the standard deviation of the probability. The standard error of the probability p is

$$\epsilon = \sqrt{\frac{p(1-p)}{n}}$$

or, for the values $p = 0.9$, we find $\epsilon = \pm 0.3\sqrt{\frac{1}{n}}$

$$p = 0.8, \text{ we find } \epsilon = \pm 0.4\sqrt{\frac{1}{n}}$$

$$p = 0.5, \text{ we find } \epsilon = \pm 0.5\sqrt{\frac{1}{n}}$$

Utilizing here the number of cases for the Hebrews and Scotch, we find the following values of the multiples of σ corresponding to $p \pm \epsilon$:

p.	$\epsilon.$		Multiple of $\sigma.$			
	Hebrew.	Scotch.	Hebrew.		Scotch.	
			$p-\epsilon.$	$p+\epsilon.$	$p-\epsilon.$	$p+\epsilon.$
0.9.....	± 0.005	± 0.014	+1.25	+1.31	+1.21	+1.37
0.8.....	± 0.006	± 0.018	+0.82	+0.86	+0.78	+0.91
0.5.....	± 0.008	± 0.023	-0.02	+0.02	-0.06	+0.06

The series of equations for $a_1, a_2, \sigma_1, \sigma_2$, have been weighted in this manner, and thus the result has been obtained.

$$\begin{aligned} \sigma_2 &= 1.16\sigma_1 \\ a_1 - a_2 &= 0.16\sigma_1 \end{aligned}$$

For Bohemian and Hebrews the following results have been obtained:

$$\begin{aligned} \sigma_3 &= \sigma_1 \\ a_1 - a_3 &= 0.94\sigma_1. \end{aligned}$$

For Sicilians and Hebrews the results are:

$$\begin{aligned} \sigma_4 &= 1.1\sigma_1 \\ a_1 - a_4 &= 0.75\sigma_1. \end{aligned}$$

With these reductions the following values for hair-colors, measured from the Hebrew average and with the Hebrew standard variability, have been obtained:

TABLE 26.—Comparison of numerical values of hair-colors, as obtained from different nationalities.

Unfortunately the extreme ashen blond is so rare in our series that no definite numerical value can be ascribed to it. For this reason we will assume the darkest black as the zero point of our series and divide the whole range from black to a very light blond—not quite ashen blond—into twenty equal divisions. Deducting, therefore, the multiple of σ in the preceding table from the value for the darkest black (1), we find the following numerical values for our hair samples:

TABLE 27.—*Absolute numerical values of hair-colors.*

Number of hair-color.	In multiples of σ .	In numerical values.	No. of hair-color.	In multiples of σ .	In numerical values.

The dark colors are farther apart than seems desirable, while the middle colors are unnecessarily numerous. In our calculations the values here given will be utilized.

CHAPTER IV.

RELATIONS BETWEEN BODILY FORM AND PERIOD OF IMMIGRATION.

The summary tables given on pages 10-23 and on page 56 show that differences exist between the physical form of immigrants and that of their descendants. It is necessary to investigate these changes more fully, particularly in regard to their probable causes and in regard to the question whether they are cumulative; that is to say, whether they increase with the time elapsed between the immigration of the parents and the birth of their children born in America. For this purpose we will first of all investigate the characteristics of the Hebrew immigration.

The Hebrew material which has been collected by us consists very largely of immigrants from Russia, Austria, and Roumania, with a comparatively speaking small number of descendants of west European Jews.

It has been shown by Dr. Maurice Fishberg ^a that Hebrews from different parts of eastern Europe show appreciable differences in type. For this reason I tried first to subdivide the material collected by us according to the origin of the people from different parts of Russia, Galicia, Roumania, etc. The results of this tabulation may be summarized as follows:

TABLE 28.—Average measurements of Hebrews born in various parts of eastern Europe.

	Roumania.	Galicia.	Little Russia.	White Russia.	Poland.	Lithuania.
Stature, cm.....	164.8	163.6	165.6	163.8	163.5	164.0
Length of head, mm.....	185.3	185.3	187.6	188.1	188.2	190.5
Width of head, mm.....	154.4	156.1	156.4	154.3	156.6	154.9
Cephalix index.....	83.4	84.3	83.5	82.1	83.3	81.1
Width of face, mm.....	139.4	140.3	140.0	139.3	140.0	139.5

The full material from which these averages are derived will be found in Table XVII of the Appendix (pp. 370-373). The differences between various types found by our observers agree well with those described by Dr. Fishberg.

The results of this classification, however, were not quite satisfactory on account of the frequent cases of mixture, intermarriages between Polish and Russian Jews from various parts of the Russian Empire being quite numerous. Furthermore, the composition of the immigrant population subjected to measurement, when distributed according to provinces and to year of arrival in America, did not show material changes in the proportionate number of individuals from each province for different years. For this reason it seemed best to treat the material as a unit, and rather to determine the physical characteristics of the immigrants arriving here from year to year. Table 11 and figure 37 (pp. 65, 66) show the results of this inquiry, the details of which are contained in Table XVIII of the Appendix (pp. 374-380).

^a Materials for the Physical Anthropology of the Eastern European Jews. *Memoirs of the American Anthropological and Ethnological Societies*, Vol. I, pp. 1-146.

The values given in Table 11 (p. 65) have been obtained by combining the differences for men and women from the norm of the whole series for each sex. The changes in the amounts of measurements for different periods are, however, so irregular, that even with the numbers thus obtained no very clear results appear. It would seem that, on the whole, there has been a decrease in length of head, width of head, and width of face, since the middle of the past century, but the change that has taken place is rather slight. A feature that is particularly noticeable is the general drop of all the absolute measurements after the year 1894. An attempt to combine all the material, adult and children, for these years, brings out the sudden drop after 1893 even more clearly; and a similar phenomenon is repeated between the years 1907 and 1909. For this reason I am inclined to believe that the type of immigrants is directly affected by financial panics. This can be due only to a selection which takes place in Europe, and which may also be affected by the return emigration from the United States to Europe. The material, so far as it has been discussed, does not give a definite answer to this important question, the solution of which would require a series of parallel measurements taken in Europe.

On the whole, it will be noticed that the general trend of change in the length of head, width of head, and width of face, among immigrants arriving at different periods, is about the same; namely, a general decrease from earlier times to later times.

These data relating to the change of type of the immigrant are important in a study of the differences between American-born and foreign-born individuals. It will readily be seen that individuals of the same age, born in America and born abroad, and belonging to the same race, represent immigrants of different periods. For instance, a 20-year-old descendant of east European Hebrew extraction, born in America, must be a child of immigrants who came here before the year 1889; while an individual of the same age, born abroad, must belong to the group of immigrants arriving after 1889. The following tables (29 and 30) illustrate clearly the difference in period of arrival of foreign-born and of the mothers of American-born of the same ages.

If there is a difference in the type of immigrants of different periods, it might be expected that these differences will be reflected in the types of American-born and foreign-born individuals of the same age. Since we find a slight general decrease in the values of the head measurements, which continues from the period before 1880 up to the present time, it might be inferred that the average measurements of American-born individuals would be a little higher than those of foreign-born individuals. The actual comparison of American-born and foreign-born individuals shows, however, that the length of head of the American-born is greater than that of the foreign-born, and that the absolute width of head and width of face of the American-born are less than the corresponding measures of the foreign-born. These results have been summarized before in Table 4 (pp. 18, 19) and figures 13, 18, and 28 (pp. 35, 40, and 50). The full data will be found in Tables VII and VIII of the Appendix (pp. 246 et seq.). The increase in the length of head and the decrease in the width of head have the effect that the cephalic index of the American-born Hebrew is less than the cephalic index of the foreign-born Hebrew of the same age.

^a Not included in number of cases and average.

In discussing this result, it seems, first of all, desirable to investigate whether the apparent change of type that takes place in America becomes more pronounced with time. In order to investigate this question, I have tabulated the measurements of those individuals who were born in America ten years and more after the arrival of their mothers. The details of this tabulation will be found in Table XIX of the Appendix (pp. 381-386). In order to gain a clear insight into the characteristics of these measurements I have compared the three groups with the general characteristic measurements of each age. The general measurement was obtained as an average of the whole series. The average values for the foreign-born, and for that group of American-born born less than ten years after the arrival of the mother, and for those born ten or more years after the arrival of

the mother, were calculated, and the difference between each of these averages and the general average was determined. The results of this tabulation are contained in Table 8 (pp. 58, 59) and figure 34 (p. 60). These tables show very clearly that the change in type is progressive with time. The differences between the foreign-born and those born ten years and more after the arrival of the mother are throughout greater than the differences between the foreign-born and those born less than ten years after the arrival of the mother. It would seem that the effect of American environment takes place almost immediately after the arrival of the parents, and that the later effect is, comparatively speaking, slight. This is expressed by the fact that the difference between the foreign-born and those born less than ten years after the arrival of the mother is greater than the difference between the two American-born groups. This fact comes out very clearly in the following table:

TABLE 31.—*Comparison of foreign-born and American-born Hebrews, born more or less than ten years after arrival of mother.*

	Average differences between total series observed and—		
	Foreign-born.	American-born.	
		Born less than 10 years after arrival of mother.	Born 10 years or more after arrival of mother.
Length of head, mm.....	-1.7	+0.2	+1.0
Width of head, mm.....	+1.3	-0.1	-0.9
Cephalic index.....	+1.2	-0.2	-1.0
Width of face, mm.....	+0.8	-0.2	-0.3
Stature, cm.....	-1.1	-0.1	+1.1
Weight, kgm.....	-0.4	-0.1	+0.6

I have introduced in this table also the differences in stature and weight, and it is noticeable that in these two cases the effect of American environment seems to continue much longer and more markedly than in the other cases.

I have also approached the problem of the increasing effect of American environment upon the descendants of immigrants by another method. The determination of the decrease of the cephalic index during the period of growth, which will be found discussed on pages 137 et seq., has made it possible to determine the characteristics of the general change in type of the descendants of immigrants with greater accuracy than has been done heretofore. I have tabulated the measurements of American-born individuals according to the number of years elapsed since the immigration of the mother, and of the foreign-born individuals according to their own ages at the time of their immigration; in other words, according to the number of years elapsed between their birth and their immigration. All the boys have been reduced to adult forms by assuming a decrease of 0.15 per year for the cephalic index up to the twentieth year.

The following table gives the results obtained for the Hebrews. The original material on which this statement is based will be found in the Appendix, Tables XX and XXI (pp. 387-411). The table given below shows clearly a gradual decrease of cephalic index after immigration.

TABLE 32.—Cephalic index of American-born Hebrew males (reduced to adults) according to time elapsed since immigration of mother.

Number of years born after immigration of mother.	Cephalic index.	Cases.	Number of years born after immigration of mother.	Cephalic index.	Cases.

			29.....	78.9	6
			United States.....	79.7	219

The change in type from the time of immigration on may be expressed by the formula

$$c_t = 82.0 - 0.08t,$$

where c_t is the index for the time t elapsed between the immigration of the mother and the birth of the child. It will be noticed that the second generation of descendants of immigrants has the type which would belong to the first generation born thirty years after the arrival of the mother.

Foreign-born boys arranged according to their own ages at the time of their immigration—in other words, according to the time elapsed between their birth and immigration—show the following values of the cephalic index reduced to adult types.

TABLE 33.—Cephalic index of foreign-born Hebrew males (reduced to adults) according to age at time of immigration.

Number of years born before immigration.	Cephalic index.	Cases.	Number of years born before immigration.	Cephalic index.	Cases.

10.....	82.7	62	1.....	83.4	47
			0.....	82.4	48

The change in type from the time of immigration may be expressed by the formula

$$c_t = 83.2 - 0.018t.$$

It will be seen that the graphical representation (fig. 35*a*, p. 62) as well as the formula indicates a very sudden break at the time of immigration, which is bridged only by the measurements of those born in the year of immigration. Considering the uncertainty of information, it may well be that in this year the country of birth is not reported with adequate accuracy, and that in reality the drop from the level of 83.2 to 82 is quite abrupt.

In interpreting these results we have to consider that children of various ages born in America will exhibit an influence upon the cephalic index dependent upon the average time elapsed since immigration of the mothers. In order to eliminate the varying effect of this cause upon children of different ages I have tabulated the average time elapsed since immigration of the mother for American-born children of different ages.

The correction of the cephalic index for each year, entered in the following table, has been obtained by multiplying the number of years elapsed since immigration by 0.08 (see p. 105).

TABLE 34.—Number of years elapsed between immigration of mother and birth of American-born child (Hebrews).

Age (years).	Average number of years when immigration occurred before birth of child.	Corresponding correction for the cephalic index.	Cases.
5.....	9.0	+0.7	45
6.....	8.2	+0.6	37
7.....	9.7	+0.7	46
8.....	8.6	+0.7	57
9.....	11.2	+0.9	119
10.....	10.1	+0.8	236
11.....	9.6	+0.8	287
12.....	8.6	+0.8	322
13.....	8.9	+0.8	304
14.....	8.2	+0.6	282
15.....	7.4	+0.6	166
16.....	6.3	+0.5	31
17.....	11.9	+1.0	16
18.....	6.0	+0.5	2

This table shows that on the average the cephalic index of American-born individuals must be increased by 0.7 in order to reduce the data to the values of individuals born immediately after the arrival of the mother; or, in other words, the uncorrected values refer to children born on the average about nine years after the immigration of their mothers.

In order to eliminate another source of error, it seems necessary to investigate more fully the types of immigrants which come to America in different years. The change in type of Hebrew immigrants has been discussed before (pp. 65, 100, Appendix, Table XVIII),

based entirely on observations of foreign-born adults. More extended material may be obtained by reducing foreign-born children to the adult foreign-born standards, in accordance with the data discussed on page 137 et seq. For purposes of comparison the whole series of American-born individuals has been reduced to the standard of American-born adults. In one column these reductions have been made without reference to the time elapsed since the immigration of the mother; in the second column all these observations have been reduced to the time of immigration, in accordance with the data given on page 105. The table (35, p. 108) is arranged in the following manner: The first column contains the year of immigration of the individual or of its mother. The second column contains the cephalic index of the foreign-born reduced to the adult type, according to age and sex. For males the annual reduction from 5 to 20 years has been assumed as 0.15; for females the same reduction has been assumed from 5 to 17 years, and an additional amount of 0.5 has been subtracted in order to reduce the female type to the male type. The third column contains the cephalic index of American-born, with the reduction for sex and age. The fourth column contains the same values corrected for sex, age, and year of immigration. In the fifth column the average number of years elapsed since immigration, and the number of cases of American-born, are given. Columns 6 and 7 contain, respectively, the differences between columns 3 and 2 and columns 4 and 2; in other words, the differences between the American-born type, excluding correction for time elapsed since immigration, and the foreign-born type, and the difference between the American-born type reduced to the time of immigration, and the foreign-born type. In column 8 the weights of these differences have been given. Column 6 shows very clearly the gradual increase of the difference between the types of American-born and foreign-born for the earlier years of immigration. This is due to the fact that at this period the time elapsed since immigration and the birth of the American-born individual is much longer than for the later years. Thus the cumulative effect of American environment is brought out with great clearness. It also appears that the values in column 7, which have been corrected for the interval between immigration and birth, are fairly constant. The average of the values of column 7 is -0.7 . The calculation of the same difference according to the method discussed before (see pp. 105, 106) would give us a difference of -1.2 . These tables show definitely that the differences between American-born and foreign-born are not due to a different composition of the body of immigrants at different periods, and they emphasize the cumulative effect of the environment. Column 2 shows very slight differences only in the cephalic index of the immigrants, so that it would seem permissible to assume that no changes in this respect have taken place during the Hebrew immigration from 1870 up to the present time. In fig. 38 (p. 68) have been plotted the values contained in columns 2 and 3.

9.....	80.4 12	77.9 17	78.9	29					

This table may be represented by the formula

$$c_t = 78.9 + 0.04t$$

and it appears therefore, that there is a slight continued increase of the cephalic index, in accordance with the time elapsed between the immigration of the mother and the birth of the child. Unfortunately, in the Sicilian series the number of individuals born a considerable number of years after the arrival of the mother is very small, and for this reason the change in type does not appear very clearly. It will, however, be shown (p. 111) that in all probability the change in type after immigration is more marked than the present table seems to suggest.

An investigation of the cephalic index of foreign-born is given in the following table:

TABLE 37.—Cephalic index of foreign-born Sicilians (reduced to adult males).

Number of years born before immigration.	Cephalic index.			Total cases.	Number of years born before immigration.	Cephalic index.			Total cases.
	Males.	Females.	Com- bined.			Males.	Females.	Com- bined.

25.....	77.9 44	77.3 26	77.7	70	0.....	78.6 25	77.8 14	78.3	39
24.....	77.8 40	77.6 42	77.7	82					
23.....	77.7 44	77.9 40	77.8	84					
22.....	77.4 39	78.2 38	77.8	77					
21.....	77.2 30	77.2 37	77.2	67					

For the period from 0 years to 18 years this series may be represented by the formula

$$c_t = 78.0 - 0.04t.$$

The full table shows, however, clearly that the rate of decrease in the cephalic index is due only to the apparent changes which occur in children a few years old at the time of immigration. When we disregard these, the cephalic index remains practically constant. It might seem that this indicates an influence of American environment upon the young American child which was not noted in the Hebrew series. An investigation of the original records shows, however, a peculiar uncertainty in regard to the place of birth in many cases where the child was born near the time of immigration. This is due to the frequent habit of the Italians to go back and forth between Italy and America before settling here. In many of these cases the answers regarding the birthplace of the child were contradicted by the statement regarding the year of immigration of the mother, and a considerable number of errors seem to have occurred in the collection of these data.

It might also be supposed that among the children born a few years before their own immigration into this country there are a considerable number whose father had lived here, and where, owing to this fact, the mode of life had undergone certain changes; but, since no data are available showing definitely that such influences did occur, it seems fully satisfactory to assume that the uncertainty in regard to place of birth, for those born near the time of immigration of the family, accounts satisfactorily for the irregularities.

It has been shown before (p. 109) that the average time elapsed since immigration of the mother of American-born children of different ages must be considered, and that a certain correction for the cephalic index has to be made in accordance with the period elapsed. The results of this tabulation are given here.

TABLE 38.—Correction for number of years elapsed between immigration of mother and birth of American-born child (Sicilians).

18 years.....	2.4 5	3.5 15	3.2 20	-0.1

Finally, I have tabulated the type of Sicilian foreign-born and American-born according to the year of immigration (Table 39, fig. 38*b*, p. 68). The table is analogous to Table 35, p. 108.

TABLE 39.—Cephalic index of Sicilians (reduced to adult males) according to year of immigration.

1. Year of immigration.	2. Cephalic index of foreign-born reduced to adult type according to age and sex.				3. Cephalic index of American-born, reduced for sex and age.	4. Ceph. index of Ameri. born, reduced for sex, age and immigration.	5. Average number of years since immigration, and number of cases of American-born.	6. Difference between columns 3 and 2 (d).	7. Difference between columns 4 and 2.
	(a) Males.	(b) Females.	(c) Children.	(d) Combined.					
	Cases.	Cases.	Cases.	Cases.					
1885	76.0 1	74.6 3	74.9 4	79.8	79.3	13.5 11	+4.9	+4.4
1886	78.0 1	77.6 7	77.6 8	79.4	78.9	11.7 9	+1.8	+1.3
1887	76.6 8	75.7 7	76.2 15	81.6	81.2	10.6 18	+5.4	+5.0
1888	80.5 4	77.7 7	78.7 11	78.9	78.5	10.1 19	+0.2	-0.2
1889	77.3 14	76.9 19	77.0 33	79.5	79.2	8.5 56	+2.5	+2.2
1890	75.8 10	77.1 6	76.3 16	79.8	79.5	7.8 27	+3.5	+3.2
1891	77.5 20	76.9 21	77.2 41	79.7	79.4	8.1 50	+2.5	+2.2
1892	77.1 19	77.4 21	74.6 1	77.1 41	79.4	79.2	5.8 38	+2.3	+2.1
1893	76.5 13	77.2 20	76.5 3	76.8 36	79.2	79.0	5.1 52	+2.4	+2.2
1894	77.4 11	76.1 11	77.5 5	76.9 27	78.5	78.3	3.9 29	+1.6	+1.4
1895	77.2 25	77.8 23	77.8 9	77.5 57	79.6	79.4	5.0 56	+2.1	+1.9
1896	78.2 17	76.6 32	78.0 15	77.3 64	79.4	79.3	3.1 42	+2.1	+2.0
1897	77.0 21	76.3 32	76.1 10	76.4 63	78.4	78.2	3.9 35	+2.0	+1.8
1898	78.0 34	77.1 40	77.4 36	77.5 110	77.8	77.7	3.5 37	+0.3	+0.2
1899	78.6 44	78.3 56	77.2 43	78.0 143	78.4	78.3	2.8 40	+0.4	+0.3
1900	78.0 47	77.5 58	78.0 44	77.8 149	78.6	78.5	2.9 29	+0.8	+0.7
1901	77.4 45	77.8 70	78.7 53	77.9 168	78.0	77.9	2.0 38	+0.1	+0.0
1902	78.0 68	77.7 78	77.8 77	77.8 223	78.6	78.5	1.6 26	+0.8	+0.7

1904	77.8 63	78.0 83	77.8 80	77.9 226	76.9	76.9	0.3 9	-1.0	-1.0
1905	77.8 80	77.5 99	77.5 106	77.6 264	78.6	78.6	0.0 1	+1.0	+1.0
1906	77.9 117	77.6 116	77.6 127	77.7 360
1907	78.0 53	78.1 87	77.5 88	77.8 223
1908	77.4 17	77.7 27	77.3 34	77.7 78
1909	77.7 42	77.1 34	77.2 32	77.4 108

The table of differences (column 6) suggests a much more marked change of type with increase of time elapsed between immigration of mother and birth of child than is obtained from the data given in Table 36 (see p. 109).

An analogous treatment of the Neapolitans, the original material for which is given in Tables XXIV and XXV of the Appendix (pp. 432-449) gives the following results (fig. 35*c*, p. 62):

TABLE 40.—Cephalic index of American-born Neapolitans, males and females (reduced to adult males).

Number of years born after arrival of mother.	Cephalic index.			Total cases.	Number of years born after arrival of mother.	Cephalic index.			Total cases.
	Males.	Females.	Combined.			Males.	Females.	Combined.	
	Cases.	Cases.				Cases.	Cases.		
0	80.1 21	80.7 7	80.2	28	10	80.2 33	83.0 17	81.1	50
1	81.3 51	82.8 34	81.9	85	11	80.1 27	83.7 20	81.6	47
2	81.3 49	82.2 29	81.6	78	12	80.7 27	82.3 20	81.1	47
3	82.0 67	81.7 55	81.8	102	13	82.4 26	80.9 19	81.7	45
4	81.2 49	83.4 34	82.1	83	14	81.8 18	82.9 11	82.1	29
5	81.6 48	81.8 39	81.6	87	15	80.8 20	81.2 8	80.9	28
6	80.7 47	81.3 32	80.9	79	16	82.1 20	81.0 7	81.8	27
7	81.4 53	81.8 20	81.5	73	17	82.3 13	81.5 3	82.1	16
8	82.5 45	81.7 25	82.2	70	18	81.7 8	81.1 8	81.4	16
9	81.3 39	79.9 21	80.8	60	19	80.0 9	79.5 2	79.9	11
					20	78.3 9	79.9 3	78.9	12
					21	80.2 3	83.1 3	81.6	6

The change of the cephalic index with the increase of time elapsed since immigration is so slight in this case that it may be disregarded.

The cephalic index of foreign-born shows also practically no change in type.

TABLE 41.—*Cephalic index of foreign-born Neapolitans (reduced to adult males) according to age at time of immigration.*

Number of years born before immigration.	Cephalic index.					Total cases.

The tabulation of the type of Neapolitan foreign-born and American born according to the year of immigration (Table 42, fig. 38c, p. 68) is analogous to the table given on page 108, and shows that the American-born type is more short-headed than the foreign-born.

TABLE 42.—Cephalic index of Neapolitans (reduced to adult males) according to year of immigration.

1. Year of immigration.	2. Cephalic index of foreign-born reduced to adult type according to age and sex.				3. Cephalic index of American-born reduced for sex and age.	4. Difference between columns 3 and 2 (d).
	(a) Males.	(b) Females.	(c) Children.	(d) Combined.

1909.....	81.5 13	80.5 16	81.8 4	81.0 33

I have not carried through a similar calculation for the Bohemians, because the difference between the cephalic index of foreign-born and that of American-born is not as marked as among the Hebrews and Italians. On the other hand, we find that among Bohemians the width of face of foreign-born and American-born shows a very marked difference. It seems, furthermore, advantageous to compare one of the characteristic traits which changes considerably during the period of growth. The width of face is favorable for a study of this kind, because its increase from 5 years up to the adult stage is quite marked. The original material for this study is given in Tables XXVI and XXVII of the Appendix (pp. 450-468).

Table 43 (fig. 40, p. 73) contains the values for width of face of adult Bohemians, males and females, arranged according to the time elapsed before the immigration of the individual, or, for the American-born, for the time elapsed between the immigration of the mother and the birth of the child. The numbers of cases for some of these years are not considerable, and for this reason I have smoothed the distribution by calculating the average for any group of three years. These smoothed values will be found in the last column of the table. They show very clearly that the width of face of the Bohemians born abroad is about 142.5 mm. Beginning with those who immigrated at the age of 10 years, and extending to those immigrating very young, a marked decrease in the width of face is noticeable, which continues among the American-born until it reaches an approximate value of 139 mm.; so that the total decrease in the width of face is nearly 4 mm.

TABLE 43.—*Width of face of adult Bohemians arranged according to number of years between immigration and birth.*

CHAPTER V.

INVESTIGATIONS OF THE CHANGE OF TYPE, BASED ON FAMILY OBSERVATIONS.

In order to overcome all possible influences of changes in the composition of the immigrant population it seems necessary to compare parents with their own children. If it can be shown that the differences between a parent and his child born abroad are not the same as the differences between a parent and his child born in America, the fact would seem to be established that an actual change of type, due to environment, takes place after immigration. In order to bring out this point, we have collected a large number of measurements of families, and we have compared the forms of the mothers and fathers with those of their own children.

The details of this investigation are given in Tables XXVIII-XXXI of the Appendix (pp. 469-508). Owing to the comparatively small number of cases in which measurements of parents and their own children have been obtained, the groups, fathers and own sons, fathers and own daughters, mothers and own sons, mothers and own daughters, are each rather small. It therefore seemed advisable, in order to bring out the results more clearly, to combine these tables into a single table showing differences between parents and children. These summarized tables are given on page 70 and more fully in Table 45.

If d expresses the difference between parent and his own child of a certain age, if the particular age is indicated by t , and f indicates foreign-born, and a American-born, then the figures entered in our table signify

$$d_{t,f} - d_{t,a}$$

In the second half of these summaries (Table 45) the observations for the different ages have been grouped together, and the measurements for the pairs of fathers and sons, fathers and daughters, mothers and sons, mothers and daughters, have been kept separate.

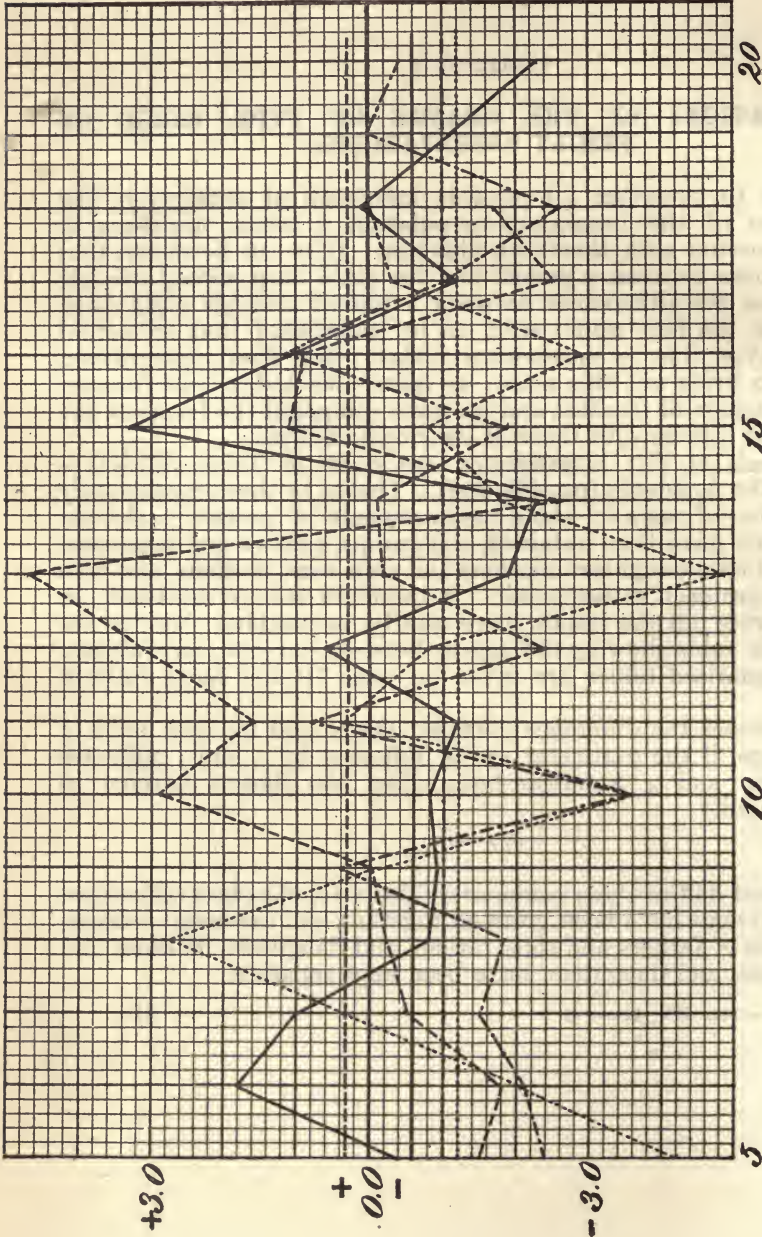

FIG. 43.—Difference in stature between parents and their own American-born and foreign-born children.

In this diagram the difference in stature between parent and his own American-born child is assumed as the norm and indicated by the zero line. The difference in stature between foreign-born child and its own parent differs from the corresponding difference between the American-born child and its parent. This difference is plotted in the diagram. The lines are irregular on account of the limited number of cases available for each year, but they show a marked tendency toward excesses or deficiencies. The average differences are plotted in the diagram by horizontal lines.

It appears that on the average the foreign-born Sicilian child is positive, while for all the others it is negative. This indicates that the foreign-born Sicilian child is shorter than the foreign-born Italian child, while among the other tribes the reverse is the case.

- Bohemian. —————
- Hebrew. - - - - -
- Sicilian. — · — · —
- Neapolitan. · · · · ·

FIG. 44.—Difference in length of head between parents and their own American-born and foreign-born children.

In this diagram the difference in length of head between parent and his own American-born child is assumed as the norm and indicated by the zero line. The difference in length of head between foreign-born child and its own parent differs from the corresponding difference between the American-born child and its parent. This difference is plotted in the diagram.

It appears that on the average the excess for the Hebrew child has a considerable negative value; for the Sicilian and Neapolitan, a considerable positive value; while for the Bohemian the difference is rather small. This shows that the heads of American-born Hebrew children increase considerably in length, while those of Sicilian and Neapolitan children decrease in length.

FIG. 45.—Difference in width of head between parents and their own American-born and foreign-born children.

In this diagram the difference in width of head between parent and his own American-born child is assumed as the norm and indicated by the zero line. The difference in width of head between foreign-born child and its own parent differs from the corresponding difference between the American-born child and its parent. This difference is plotted in the diagram. It appears that on the average the excess for Hebrews and Bohemians has a considerable positive value; for Sicilians and Neapolitans a negative value. This means that the width of head of American-born Hebrew and Bohemian children decreases, while for Sicilian and Neapolitan it increases.

Bohemian.
 Hebrew.
 Sicilian.
 Neapolitan.
 1 square = 0.2 mm.

FIG. 46.—Difference in cephalic index between parents and their own American-born and foreign-born children. In this diagram the difference in cephalic index between parent and his own American-born child is assumed as the norm and indicated by the zero line. The difference in cephalic index between foreign-born child and its own parent differs from the corresponding difference between the American-born child and its parent. This difference is plotted in the diagram. It appears that on the average the excess in cephalic index for Hebrews and Bohemians is positive; for Sicilians and Neapolitans, negative. That means that the cephalic index of the American-born Hebrew and Bohemian children decreases, while for the American-born Sicilian and Neapolitan children it increases.

Bohemian. ———
 Hebrew. - - - - -
 Sicilian. - · - · -
 Neapolitan. ·····
 1 square = .02. unit.

FIG. 47.—Difference in width of face between parents and their own American-born and foreign-born children.

In this diagram the difference in width of face between parent and his own American-born child is assumed as the norm and indicated by the zero line. The difference in width of face between foreign-born child and its own parent differs from the corresponding difference between the American-born child and its parent. This difference is plotted in the diagram. It appears that on the average the excess of width of face among all the types is positive, which means that the width of face decreases for the American-born children.

- Bohemian.
 - · - · Hebrew.
 - - - Sicilian.
 - - - - Neapolitan.
- 1 square = 0.2 mm.

The tables given here (Table 45, figs. 43-47) show very clearly a close correspondence between the results obtained by the generalizing method (see Tables 3-14) and those obtained by this individualizing method. In the group of Bohemians I have included here all the measurements of Poles, Hungarians, and Slovaks, which differ so little in type from the Bohemians and are, comparatively speaking, so few in number that it seemed the only feasible way of handling the material. Among the Bohemians we observed that the stature of the American-born is, on the average, about 0.5 cm. more than that of the foreign-born, while in all the other measurements a decrease takes place among the American-born; the length of head decreasing on the average about 0.5 mm., width of head about 1.2 mm., width of face about 1.1 mm.

Among the Hebrews we find a very decided increase of stature and increase in length of head, and decreases in width of head and width of face. Among the Sicilians the stature shows a marked decrease. A decrease may also be observed in the length of head and width of face, while the width of the head increases.

TABLE 45.—*Summary of differences between parents and their own foreign-born children and parents and their own American-born children.*^a

I have also made the same calculation for Hebrew parents and their own children born later than ten years after the arrival of the mother in the United States. The results of this tabulation are given in Table 46.

TABLE 46.—*Differences in cephalic index between American-born Hebrew children (born ten years and more after arrival of mother) and their own parents.*

A comparison between Tables 45 (2) and 46 is contained in Table 47, which shows that, on the whole, the differences between parents and their children born in America become more marked with increasing time elapsed since the arrival of the parents in America before the birth of the child. The total number of cases available for the purpose of this study is not great enough to allow us to expect great regularity in the results. The differences which are combined in this table have been weighted in accordance with the numbers of foreign-born and American-born children that have been compared for each year, and the weights thus obtained have been given here in the same way as the number of cases in previous tables.

TABLE 47.—*Excess of difference in cephalic index between American-born Hebrew children and parents over that between foreign-born Hebrew children and parents.*

Age.	I. All American-born children.		II. American-born children, born 10 years and more after arrival of mother.		Excess of II over I.
	Weight.		Weight.		
5 years.....	+2.3	27	+2.6	25	+0.3
6 years.....	+2.1	25	+2.7	19	+0.6
7 years.....	+2.1	33	+2.4	27	+0.3
8 years.....	+0.9	42	+2.1	31	+1.2
9 years.....	+1.8	38	+2.1	25	+0.3
10 years.....	+1.5	46	+1.8	30	+0.3
11 years.....	+1.5	39	+2.6	26	+1.1
12 to 14 years.....	+1.9	106	+1.6	60	-0.3
15 years and over.....	+1.0	160	+1.2	87	+0.2

A combination of these values for all ages gives the result that children born less than ten years after the arrival of their mothers in America lose 0.9 units in their cephalic index, and those born ten years or more after their mothers' arrival in America lose 1.9 units in their cephalic index, as compared to foreign-born children. In Table 31 (p. 104) the corresponding values are given, obtained from more extensive but less homogeneous material, in so far as the children have not been compared with their own parents, but the general types of foreign-born and American-born children have been compared. The table shows that children born less than ten years after their mothers' arrival in America lose 1.4 units in their cephalic index; those born ten years or more after their mothers' arrival lose 2.2 units. The values show, therefore, a satisfactory agreement.

Thus it appears that the conclusion reached from a comparison of the gross material of American-born and foreign-born individuals is sustained by the comparison between parents and their own children.

CHAPTER VI.

GROWTH.

PHYSIOLOGICAL DEVELOPMENT.

So far as our investigations show, the differences between the American-born and foreign-born types persist throughout the period of growth. No material has been collected for the first four years of life, but with the fourth year the differences appear clearly established. It might be conceived that the increase in stature of the growing Hebrew child is due to a physiological acceleration of his development as compared to the foreign-born child. Previous observations show clearly that an acceleration of development takes place with the improvement of the economic conditions of life. For this reason it seemed important to compare the general physiological development of foreign-born and American-born children. Unfortunately the limited time and means at our disposal did not permit us to carry through this investigation in such detail as is desirable, and only a rough series of observations on the pubescence of boys was taken according to the methods developed by Dr. C. Ward Crampton.

The following table shows the relative frequency of degrees of pubescence. P. I. designates the absence of pubic hair; P. II, short straight pubic hair in course of development; P. III, fairly full development of pubic hair.

TABLE 48.—*Frequency of stages of pubescence of Hebrew boys.*

Age.	Frequencies in per cent.					
	P. I.		P. II.		P. III.	
	For- eign- born.	Ameri- can- born.	For- eign- born.	Ameri- can- born.	For- eign- born.	Ameri- can- born.
10 years.....	70.7	71.8	27.0	28.2	2.3
11 years.....	61.0	72.5	34.3	26.0	4.7	1.5
12 years.....	57.3	62.3	36.0	33.1	6.7	4.6
13 years.....	42.0	41.3	37.6	41.7	20.4	17.0
14 years.....	15.2	13.8	42.4	28.0	42.4	58.2
15 years.....	13.8	7.4	17.2	15.4	69.0	77.2

It will be seen that the first column is nearly identical for American-born and foreign-born, while the period of transition from childhood to the adult stage shows certain differences. The number of cases is, however, so small that we are not justified in assuming an actual difference in the physiological development of the two divisions.

The following tables show the physical development of Hebrew children of different ages according to the degree of their pubescence. (Figs. 48-53.) (See Appendix, Table XXXII, pp. 509-525.)

The infantile types for each age are retarded as compared to the normal development of their age, and this retardation is the greater, the older the children. On the other hand, the adult type for each age is accelerated in its development, and the more so, the younger the children among whom the adult type is found. This is expressed by the fact, brought out previously by Dr. C. Ward Crampton, that the infantile type for each age is considerably smaller than the adolescent type, which again is smaller than the mature type. When the statures of these types are compared for American-born and foreign-born children, it appears that the American born are throughout taller than the foreign born of the same age and the same stage

FIG. 48.—Relation between stature and maturity.

Scale, 1 square=0.5 cm. Heavy lines indicate foreign-born; light lines, American-born.

The curves of this diagram show the statures of individuals of infantile type (P. I), of adolescent type (P. II), and of mature type (P. III). The diagram shows the great differences in stature among individuals of different grades of maturity. In each of the three groups the American-born are taller than the foreign-born. The apparent drop in stature at 15 years for the infantile and adolescent groups is due to the fact that these two groups contain excessively retarded individuals only.

FIG. 49.—Relation between weight and maturity.

Scale, 1 square=0.5 kg. Heavy lines indicate foreign-born; light lines, American-born.

The curves of this diagram show the weights in kilograms of individuals of infantile type (P. I), of adolescent type (P. II), and of mature type (P. III). On the whole the American-born is slightly heavier than the foreign-born. The apparent drop in weight at 15 years for the infantile and adolescent groups is due to the fact that these two groups contain excessively retarded individuals only.

FIG. 50.—Relation between length of head and maturity.

Scale, 1 square=0.5 mm. Heavy lines indicate foreign-born; light lines, American-born.

For explanation of curves see Fig. 48. The differences in length of head for the foreign-born and American-born of each group are greater than the differences for the three types of maturity.

FIG. 51.—Relation between width of head and maturity.

Scale, 1 square=0.5 mm. Heavy lines indicate foreign-born; light lines, American-born.

For explanation of curves see Fig. 48. The differences in width of head for the foreign-born and American-born of each group are greater than the differences for the three types of maturity.

FIG. 52.—Relation between width of face and maturity.

Scale, 1 square=0.5 mm. Heavy lines indicate the foreign-born; light lines, American-born.

For explanation of curves see Fig. 48. The differences in width of face for the foreign-born and American-born of each group are as great as the differences for the three types of maturity.

FIG. 53.—Relation between color of hair and maturity.

The curves of this diagram show that the color of hair of American-born is throughout a little lighter than that of the foreign-born, but that no material differences occur according to stage of maturity.

of development. This shows clearly that the greater size of American-born children is not entirely due to an acceleration of development. The head measurements show also the same typical differences for all stages of maturity.

According to the data contained in this table, the beginning of pubescence occurs very nearly at the same time among American born and foreign born, while maturity among the American born may be reached slightly earlier than among the foreign born, but the difference in period seems to be trifling. On the other hand, the differences in measurements persist, and these differences are so great that they can not be accounted for by the small differences in rapidity of physiological development. These facts, therefore, seem to support our conclusion that the difference between the two types is not due to the rapidity of development, but to other causes. The actual decrease in the transversal diameters of the head and in those of the face can in no way be accounted for by acceleration of development.

GROWTH OF THE HEAD.

The discussions contained on page 104 et seq. are based on a detailed study of the growth of head measurements. The results of this investigation are given in the following pages.

AVERAGE RATE OF CHANGE OF CEPHALIC INDEX.—The change of the cephalic index is so slight that up to the present time there has been no accord among investigators in regard to the question whether there is a change (decrease or increase) and whether the same changes take place in all different types of man.

For the purpose of a discussion of our material, we will assume that the change in the cephalic index proceeds at the same rate until the adult stage is reached, and we will first consider only the material collected for the present investigation.

It will be shown later on that the measurements of foreign-born and American-born individuals show certain typical differences. In the following table these measurements have been combined, the American born being reduced to the foreign-born type by adding the typical difference between the two groups (see p. 70). Table 50, on the following page, shows the observations on cephalic index of males and females:

If the value of the average for any particular year is called c_t , we may say

$$c_t = a + bt,$$

where t is assumed to be measured from the average age of the series and where a and b are certain constants.

It follows—if we indicate averages by brackets—that

$$\begin{aligned} [c_t] &= a \\ [c_t t] &= b[t^2]. \end{aligned}$$

The constants a and b have been determined in this manner.

TABLE 50.—Cephalic index, according to age.

26 years.....	84.5 669	83.6 163	82.6 131			

When we assume the rate of change in the cephalic index from 3 years to 20 years in males, and from 3 years to 18 years in females, to be constant, we find the following results by computation from the tables:

TABLE 51.—*Formulas showing decrease of cephalic index of foreign-born with increasing age.*

	Males (0-20 years).	Females (0-18 years).
Bohemian.....	86.4-0.13 <i>t</i>	86.7-0.14 <i>t</i>
Slovak and Hungarian.....	86.5-0.12 <i>t</i>	87.7-0.22 <i>t</i>
Pole.....	86.4-0.23 <i>t</i>
Hebrew.....	86.1-0.154 <i>t</i>	86.1-0.14 <i>t</i>
Sicilian.....	80.6-0.147 <i>t</i>	80.7-0.16 <i>t</i>
Neapolitan.....	83.0-0.11 <i>t</i>	84.2-0.20 <i>t</i>

To these tables may be added some others, based on observations made in various countries (see p. 78). The calculation of a few of these series according to the method outlined before gives the following results:

TABLE 52.—*Formulas showing decrease of cephalic index with increasing age.*

	Males (0-20 years).
Worcester, Mass.....	80.5-0.13 <i>t</i>
St. Louis, Mo.....	81.2-0.05 <i>t</i>
Holstein.....	84.4-0.09 <i>t</i>
Strassburg, Alsace.....	83.7-0.04 <i>t</i>

It will be seen that the rate of change in these cases, except the one for Worcester, is much lower than the one given in the preceding table. Attention may be called to the fact that the ages from which the constants have been derived are different from the ages represented in the preceding series. For Strasburg and Holstein particularly the whole period of development from birth up to the adult stage is included, while in the material collected by the immigration commission the first four years of life were excluded. It would seem, therefore, that the change in the cephalic index during the first few years of life must proceed at a slower rate than the change of the index during the later part of childhood. In St. Louis the bulk of the series lies between the years 6 and 14, while the period of adolescence is practically excluded. It may be, therefore, that the low value of the index for St. Louis is a characteristic of that period of development. It must be remarked, however, that the results of the St. Louis series, considering the great number of cases measured, is peculiarly irregular; so much so that I am inclined to think that certain irregularities must have crept into the series of observations.

DETAILED DISCUSSION OF GROWTH OF HEAD.—It would be feasible to obtain a clearer insight into the laws of growth during different periods by calculating the constants according to the method previously outlined for periods of four years instead of covering the whole period of growth.

Owing to lack of time, I have preferred to employ a different method for the purpose of determining the change in head-form. I have proceeded as follows:

The total increment for any given year up to the adult stage has been calculated from all those tables in which an adequate number of measurements of adults is available. These are particularly Bohemian (1), Slovak and Hungarian (2), Poles (3), Hebrews I (4), Hebrews II (5), Dresden I (6), Sicilian (17), Neapolitan (18), Scotch (19). The weight for each increment was determined from the number of cases (n_1) for the particular year and for the adults (n_2), according to the formula.

$$w = \frac{n_1 n_2}{n_1 + n_2}$$

After the characteristic increment for each year had been obtained in this manner these increments were applied to all the remaining series for which no adult measurements were available, and the adult measurements were reconstructed for these series by adding to each year the characteristic amount of growth and taking the average of all the values thus obtained according to the weights for each year: for instance, for Dresden I (6) the following calculation for length of head might be made:

TABLE 53.—Length of head of adult males, Dresden I, calculated from measurements of children.

Age.	Milli- meters.	Age.	Milli- meters.
10 years.....	185.5	16 years.....	187.7
11 years.....	185.7	17 years.....	188.3
12 years.....	186.0	18 years.....	188.0
13 years.....	185.8	19 years.....	188.0
14 years.....	186.2	20 years.....	188.1
15 years.....	187.6		

I have selected this table because it shows clearly that the results obtained from the whole series are not strictly applicable in the present case. The length of head of the adult obtained from the measurements of children from 10 years up shows a constant and regular increase, proving in this manner that the rate of growth from 10 years up for the series Dresden I is greater than that of the typical series here obtained. In this manner it is possible to control the results of the various series and to determine whether characteristic differences exist between each particular series and the general series that has been obtained. I will now proceed to discuss the various head-measurements according to this method.

Length of head.—Following is the combined table for the increase of the length of the head from each year up to the adult stage, and based on the same material as was utilized for the discussion of the cephalic index (pp. 145-147).

TABLE 54.—*Increments of length of head of males (from all available material).*

Interval.	Increment.	Weight.	Increment smoothed.	Annual growth.
	<i>Mm.</i>		<i>Mm.</i>	<i>Mm.</i>
3 to 26 years.....	21.1	35	21.1	
4 to 26 years.....	19.4	99	19.3	1.8
5 to 26 years.....	17.4	297	17.7	1.6
6 to 26 years.....	16.3	810	16.2	1.5
7 to 26 years.....	15.0	1,060	15.1	1.1
8 to 26 years.....	14.0	1,036	13.9	1.2
9 to 26 years.....	12.8	1,171	12.9	1.0
10 to 26 years.....	11.9	1,483	12.0	0.9
11 to 26 years.....	11.2	1,136	11.2	0.8
12 to 26 years.....	10.4	1,862	10.2	1.0
13 to 26 years.....	8.9	1,672	9.0	1.2
14 to 26 years.....	7.6	1,442	7.5	1.5
15 to 26 years.....	6.1	722	5.9	1.6
16 to 26 years.....	4.0	751	4.3	1.6
17 to 26 years.....	2.8	476	2.7	1.6
18 to 26 years.....	1.3	289	1.7	1.0
19 to 26 years.....	1.0	213	0.9	0.8

It appears clearly that the growth of the length of the head shows the same characteristics that have been observed in the rate of growth of stature and weight. During the first few years of life there is a decided decrease in the rate of growth, which lasts until the eleventh year. From this time on there is a very decided increase in the rate of growth, which reaches its maximum at the sixteenth year; and from this time on the decrease in the rate of growth is very rapid until the adult stage is reached.

The general curve does not fit all the series, and there is good evidence that the rate of growth is not the same in all the groups. Among Dresden I boys (6) the acceleration begins about a year and a half earlier than among the whole series and has the effect that the total amount of growth is greater than in the general series. The boys represented by this series are gymnasium pupils, and represent, therefore, a selected class. It will be remembered that all investigations have shown that classes which are socially in more favorable position develop more quickly than others, and also that the total amount of growth attained by them is greater than that attained by classes which are retarded owing to unfavorable conditions. The growth of the head of Dresden boys is therefore quite in accord with the observations made on the whole bulk of the body.

Among the Hebrew boys (5) the amount of growth in length of head that remains to be done after the age of 9 years is about 1 mm. less than among the grand average. It is doubtful whether this phenomenon is accompanied by a greater growth during the pre-

ceding period, although it suggests a longer continuance of the more rapid growth of early childhood.

Among the Bohemians a considerable amount of growth occurs after the fifteenth year. The whole series is rather irregular, which is accounted for by the small number of cases; but up to the sixteenth year the average difference between the total series and the combined Bohemians, Slovaks, Hungarians, and Poles is 1.4 mm., the amount of growth to be accomplished by the Bohemian series being more than that of the general series. The material is not sufficient to show whether the period of acceleration is earlier in this case or whether we are simply dealing with a longer continuation of growth from 18 years on.

The Sicilians exhibit quite different conditions of growth. The series of observations demonstrates very clearly that the total amount of growth from 5 years on up to the adult stage is less from year to year than in the whole series. There is no earlier appearance of the period of acceleration than in the rest of the series; in other words, the total amount of growth for every year is less than among the rest of the observed series. The conditions among the Neapolitans are somewhat similar to these, but not quite so marked.

If we assume the general series to represent the type of development for Europeans, and if we assume the differences between any particular series and this general series to be an indication of the peculiar character of development of each group, the following separate groups may be isolated:

TABLE 55.—*Increments of length of head of males in different European groups.*

Similar results are obtained from the analogous tabulation of the measurements of length of head of females. These are summarized in the following table (see also p. 78):

TABLE 56.—*Increments of length of head of females (from all available material).*

Interval.	Increment.	Weight.	Increment smoothed.	Annual growth.

18 to 26 years.....	1.3	190	1.4	0.4
19 to 26 years.....	1.0	162	1.0	0.0

Here also we may notice a very rapid increase in the rate of growth, which culminates between 12 and 13 years, while among males the culmination is near the fifteenth year. After this the rate of growth decreases very rapidly.

Width of head.—The tabulations for the growth of width of head of males and females have been made in exactly the same manner as those just described. The summary of these tables is given in table 57 (see also p. 78):

The amounts of growth for width of head, although slightly irregular, show also that a minimum in the rate of growth prevails during the pre-adolescent period, and that during the period of adolescence the rate shows the same kind of a maximum which has been observed in the measurements of stature, weight, and length of head.

Cephalic index.—The tabulation of the cephalic index, based on the same material which we utilized for discussing the development of the length of head and width of head, is contained in Table 58 (see also p. 78). It will be noticed that the cephalic index from the fourth year to the tenth year is practically constant; that during the period of adolescence a sudden decrease in the cephalic index occurs, which is presumably coincident with the development of the frontal sinuses, and the dependence of which upon the change in length of head and width of head may be seen by a comparison with the two preceding tables. With the twentieth year the cephalic index has practically reached its final value.

CHAPTER VII.

HEREDITY.

For the purposes of our investigation it is necessary to have a clearer insight into the problems of heredity in man than we possess up to the present time. In order to understand the development of the descendants of immigrants, who have been drawn from the most diverse parts of Europe, and who, in course of time, are bound to intermingle, it is necessary, first of all, to know whether the effect of mixture in man is the production of a middle type representing a type intermediate between the two parents, or whether there is a tendency in the offspring to revert either to the father's type or to the mother's type, and whether, therefore, the result of mixture of types will be an increased variability of all the individuals composing the nation.

A number of attempts have been made to solve this question, but adequate material has never been obtained. The measurements of families which have been conducted in our work for the commission have made it possible to attack this important question with considerable prospect of success. I developed the method of approach at a previous time.^a The principle of our method is the following: If the descendants of a couple revert to a middle type and do not tend to revert to the individual types of the parents, then the variability of the children must remain the same, no matter how different the parents. If, on the other hand, there is a tendency in the children to revert to the type of either father or mother, then the variability of children of the same family will increase with increasing difference of the parents. I have also shown that the average variability of a family of n children will be

$$[S_n^2] = \sigma^2(1 - r_c) \frac{n-1}{n}$$

where S_n indicates the mean square variability of the children of one family; σ , the variability of the individuals constituting the whole series; r_c the coefficient of correlation of children of the same family.

I have tabulated all our material giving measurements of parents and children, where the measurements of both parents were known, in Table 65. Since, according to the formula just given, the variabilities depend upon the number of children, they have all

been reduced to the same standard by multiplication with $\frac{n}{n-1}$. The variabilities of the children are given for various groups of parents arranged according to the difference between the cephalic indices of

^a Franz Boas, *Heredity in Anthropometric Traits* (American Anthropologist, N. S., vol. 9. [1907], pp. 453-469).

father and mother. Before making the calculation, all the indices of children and of females were reduced to the indices of adult males, in accordance with the method explained on page 139. The last column of the table gives the average variability of children, obtained for each group of parents.

Although the distribution of variabilities is not quite regular, a very rapid increase of variability of children may be observed for the higher values of differences between parents. Very little change seems to occur up to a difference of six units between father and mother; but from this point on, the values rise quite rapidly. Unfortunately, it is difficult to obtain much material for the higher values of differences between parents, because, according to the laws of probability, small differences between the parents are the norm.

From the whole table the average variability of children is obtained—

$$a = 7.23;$$

the average difference between parents—

$$D = 3.64.$$

and the variability of children approximately

$$v = 6.43 + 0.22d,$$

where d represents the difference between the parents.

Another possible explanation of the change in type of the descendants of immigrants should be considered. Such a difference between the type of American-born descendants of immigrants and the foreign-

born would develop in case there should be any mixture with Americans which is not revealed in the marriage relations. If this should actually be the case, a considerable number of instances must occur in which the alleged father of the child is not the real father. According to the laws of heredity, an occurrence of this kind would be expressed by a low coefficient of correlation between fathers and children; and the calculation of some material of this kind which I collected years ago on the North American Indians has shown that illegitimacy of descent can easily be detected by biometrical methods.^a

The sociological conditions of the immigrants in New York do not make it in the least probable that such conditions prevail here. Nevertheless it seemed necessary to make the test. For this purpose I have collected the correlation in head-form and color of hair among the Hebrews for the groups of foreign-born and American-born fathers and sons, fathers and daughters, mothers and sons, mothers and daughters.

The calculation is not quite simple, on account of the phenomena of growth, and the following method was adopted. If the measurement of a parent is called X , that of a child of a certain age Y , and the difference between the type of the parent and the type of the child of a certain age d ,

$$\begin{aligned} [(X - Y)^2] &= [(d + x - y)^2] \\ &= d^2 + [(x - y)^2]. \end{aligned}$$

The weight to be given to $[(x - y)^2]$ must be $n - 1$, because the number of cases in each group is very small. By calculating this value for each year, a general average may be obtained, which has been used as a basis for the calculation of the coefficient of correlation. Our tables show that in all the head-measurements the variabilities may be considered as constant for the whole series from 5 years up to the adult stage, the variations being very small and irregular. If we call these variabilities for parent and child σ_x and σ_y , we may therefore say

$$[(x - y)^2] = \sigma_x^2 + \sigma_y^2 - 2[xy]$$

and

$$[xy] = \frac{1}{2}(\sigma_x^2 + \sigma_y^2) - \frac{1}{2}[(x - y)^2].$$

From this value of xy the coefficient of correlation, r , can easily be obtained:

$$r = \frac{[xy]}{\sigma_x \sigma_y}.$$

In the table these values are given for the length of head, width of head, and color of hair for the Hebrews (Tables 67-69). The summary of these tables (Table 66) shows that while the coefficient of correlation shows remarkably large variations considering the number of available cases, there is no regularity, indicating that there is a loss of correlation for the American-born children when compared with their fathers, and the assumption that foreign intermixture is the cause of change of type may be finally dismissed.

^a Pearson, The Chances of Death.

I have calculated only the correlation between parents and children for length of head, width of head, and color of hair. Taking the total material together, we obtain the following correlations between parents and children:

Length of head.....	0. 383 (2,327 cases)
Width of head.....	0. 342 (2,327 cases)

For fathers and children the color of hair gives the coefficient of correlation:

Color of hair.....	0. 36 (696 cases)
--------------------	-------------------

For women the correlation of color of hair between mothers and children gives the abnormally low value of 0.22, obtained from 1,100 cases, and for mothers and their daughters this value sinks even to 0.13, obtained from 616 cases. I think that there is no doubt that this low value is due to the fact that many of the Hebrew women wear wigs, and that for this reason the color of hair is not the natural one. The three values given above, taken together, suggest that the correct value for the coefficient of correlation between parents and children among the Hebrew is 0.36.

The summary of the correlations between fathers and mothers and their sons and daughters is as follows:

TABLE 66.—*Summary of correlations between parents and children.*

		Sons.	Daughters.
		<i>Cases.</i>	<i>Cases.</i>
Father	{ Length of head.....	0. 45 478	0. 40 502
	{ Width of head.....	0. 38 478	0. 36 502
	{ Color of hair.....	0. 37 344	0. 36 352
Mother	{ Length of head.....	0. 28 626	0. 41 721
	{ Width of head.....	0. 35 626	0. 35 721
	{ Color of hair.....	0. 30 524	0. 13 616

These columns indicate, perhaps, that the similarity between parents and children of the same sex is a little greater than the similarity between parents and children of the opposite sex; but this result seems hardly sufficiently certain to be accepted as final.

The detailed tables (Tables 67-69) may be summarized as follows: The comparison between the correlations between fathers and foreign-born children and fathers and American-born children shows no loss in the correlation among the American-born. It is, however, somewhat striking that the correlation between parents and American-born children is very much more variable than the correlation between parents and foreign-born children, and it does not seem impossible that we may recognize in this variability the effect of a disturbing factor.

CHAPTER VIII.

STATURE OF CHILDREN IN FAMILIES OF DIFFERENT SIZES.

On account of the marked reduction in size of families among Americans and the descendants of Americans, it seemed important to investigate the relation between physical development and the size of family. The material for this investigation is contained in statistics collected by me in 1892 in Toronto, Ontario, and in Oakland, Cal. In Tables XXXIV and XXXVI of the Appendix (pp. 546, 547, 572, 573) the distribution and average of statures of the Toronto and Oakland children are given for those individuals for whom the number of living brothers and sisters is known.

In Tables 70 and 71 the average statures of children of families of certain sizes are compared with the average statures of all the children of the same age. The material on which these tables are based is contained in Tables XXXIII (pp. 526-545) and XXXV (pp. 548-571) of the Appendix, and the comparison has been made in the following manner. The average stature of children belonging to families of one, two, three, etc., living children have been obtained and subtracted from the average stature of all the children of the same age according to the data contained in Tables XXXIV and XXXVI of the Appendix. These differences are not comparable for children of different ages, because the variability of stature shows very great differences during the period of growth. In order to make the values obtained from different ages comparable, they have been reduced to multiples of the standard variability of each year, and these data are contained in our present tables. The tables may be summarized by averaging the differences for all the years and for each size of family. This summary is contained in Table 72 (fig. 42, p. 80).

The average number of children in Toronto and in Oakland is not quite the same, but the correction for the average stature of the family due to this cause is very slight only, and it seems justifiable to combine the two tables into one. It will be seen from these data, which are contained in the preceding table, that the stature of children in families having one child only is considerably above the average, and that with increasing number of children the average stature first decreases quite rapidly; in large families, however, quite slowly.

An attempt to correlate stature in the same way with the number of deceased children in a family shows a much slighter correlation. The average stature decreases slightly with the number of deceased children, but the calculation has not been carried through in detail.

I pointed out at a previous time ^a that first-born children are taller than later-born children, and that among the Toronto children the difference in favor of the first-born is 0.36 cm. From the data obtained by the classification of families according to size, it would seem that the excess in stature of the first-born children is essentially due to the fact that they contain a great many children belonging to small families, while later-born children belong on the whole to larger families. The difference in the case of children classified according to size of family is ever so much greater than the difference according to order of birth.

I have also attempted to classify the families according to occupation of parents, in order to discover whether any material difference in the size of family exists between the different occupations. This classification has, however, not led to any result showing differences, so that we may conclude that without regard to social position the same relation exists, and that on the whole children in small families are physically better developed than children in large families.

^a The Growth of Toronto Children (Report of the Commissioner of Education for 1896-97 [Washington 1898], p, 1596).
